The influence of exogenous ACTH on the levels of corticosterone and cortisol in the plasma of young chicks (Gallus domesticus). Kalliecharan R. **Gen Comp Endocrinol** 1981 Jun;44(2):249-51

Chronic and acute stress interrelationship: corticosterone response. Armario A, et al. **Horm Metab Res** 1981 Jul;13(7):413-4

Effects of sodium loading, desoxycorticosterone acetate, and corticosterone on urinary kallikrein excretion. Bönner G, et al. **Horm Res** 1981;14(2):87-94

Circadian periodicity of plasma corticosterone levels in rats subjected to hemorrhagic shock and surgical trauma. Levine RL, et al. **Horm Res** 1980;13(6):385-95

A simultaneous radioimmunoassay for aldosterone and its precursors: human plasma levels following the inhibition of converting enzyme, before and after blockade of prostaglandin biosynthesis. Witzgall H, et al. **J Clin Chem Clin Biochem** 1981 Jun;19(6):387-94

Binding of steroids by proteins in follicular fluid of the human ovary. Martin B, et al. **J Clin Endocrinol Metab** 1981 Aug;53(2):443-7

Protein-bound cyclic AMP and steroidogenesis in the adrenal gland of the rat. Guillemant J, et al. **J Endocrinol** 1981 Jul;90(1):77-82

Effect of glucocorticoids, butanol extraction of serum and adrenalectomy on somatomedin levels in the rat. Holder AT, et al. **J Endocrinol** 1981 Sep;90(3):411-20

Corticosterone catabolism by mouse liver homogenate: strain difference in dependence on added NADP. Shire JG. **J Endocrinol Invest** 1981 Apr-Jun;4(2):193-6

Effects of septic shock plasma on adrenocortical cell function. Keri G, et al. **Life Sci** 1981 Apr 27;28(17):1917-23

The effects of predictable and unpredictable schedules of physical restraint upon rats. Quirce CM, et al. **Life Sci** 1981 Apr 27;28(17):1897-902

Central epinergic inhibition of corticosterone release in rat. Roth KA, et al. **Life Sci** 1981 May 21;28(21):2389-94

Preferential accumulation of [3H] corticosterone in chick brain during embryonic development. Gremo F, et al. **Neurochem Res** 1981 Apr; 6(4):343-51

Effect of intrahypothalamic implantation of cortisone acetate on the onset of circadian corticosterone rhythm in neonatal female rats. Miyabo S, et al. **Neuroendocrinology** 1981 Jul;33(1):47-51

Phase relation between episodic fluctuations of spontaneous locomotor activity and plasma corticosterone in rats with suprachiasmatic nuclei lesions. Watanabe K, et al. **Neuroendocrinology** 1981 Jul;33(1):52-9

Hypothalamic multiunit activity correlates of the adrenocortical response to stress. Ramade F, et al. **Neurosci Lett** 1981 May 29;23(3):297-302

Labelling of Schwann and satellite cells by [3H]dexamethasone in a rat sympathetic ganglion and sciatic nerve. Warembourg M, et al. **Neuroscience** 1981;6(6):1039-43

Corticosterone response in group-housed rats exposed to psychogenic stresses in different social conditions. Armario A, et al. **Physiol Behav** 1981 Jul;27(1):179-81

Locomotor activity, defecation score and corticosterone levels during an openfield exposure: a comparison among individually and group-housed rats, and genetically selected rat lines. Gentsch C, et al. **Physiol Behav** 1981 Jul;27(1):183-6

Humoral indices of stress in rats. Natelson BH, et al. **Physiol Behav** 1981 Jun;26(6):1049-54

Effects of housing on corticosterone rhythm and stress responses in female mice. Nichols DJ, et al. **Physiol Behav** 1981 Jul;27(1):1-5

Circulating levels of corticosterone in the serum of developing chick embryos and newly hatched chicks. Scott TR, et al. **Poult Sci** 1981 Jun;60(6):1314-20

Corticosteroidogenesis in vitro: effects of parathyroid hormone, ACTH, and calcium. Carsia RV, et al. **Proc Soc Exp Biol Med** 1981 Jul; 167(3):402-6

Enzymatic changes in rat thymus after intraperitoneal injections of adrenocorticotrophic hormone and corticosterone. Deschaux P, et al. **Thymus** 1981 Apr;2(6):299-304

Changes in certain diurnal hormonal rhythms in developing male rats exposed to adiurnal environmental cues. Ooka-Souda S. **Mech Ageing Dev** 1981 Mar;15(3):227-33 (eng)

[Effect of calcium and magnesium ions on the interaction of corticosterone with the cytosol receptor(s) in the rat brain] Ueda M. **C R Trav Lab Carlsberg** 1981;175(3):372-6 (Eng. Abstr.) (Fre)

[Reaction between steroid hormones, the liver and its plasma membrane] Denisov IuP, et al. **Biull Eksp Biol Med** 1981 Jun;91(6):722-5 (Eng. Abstr.) (Rus)

CORTICOTROPIN

Immunohistological demonstration of ACTH-like immunoreactivity in the foetal adrenal medulla in the 23rd week of gestation. Ito S, et al. **Acta Endocrinol (Copenh)** 1981;97(3):412-8

beta-Adrenergic stimulation of the release of ACTH- and LPH-related peptides from the pars intermedia of the rat pituitary gland. Tilders FJ, et al. **Acta Endocrinol (Copenh)** 1981;97(3):343-51

Effects of prolonged ACTH treatment on adrenal steroidogenesis and blood pressure in rats. Vazir H, et al. **Acta Endocrinol (Copenh)** 1981 Aug;97(4):533-42

Effects of an ACTH short chain neuropeptide in man. Dornbush RL, et al. **Am J Psychiatry** 1981 Jul;138(7):962-4

Strain differences in pituitary beta-endorphin and ACTH content in inbred mice. Crabbe JC Jr, et al. **Brain Res** 1981 Aug 24; 219(1):219-23

Pineal protein synthesis highly sensitive to ACTH-like neuropeptides. Schotman P, et al. **Brain Res** 1981 Aug 24;219(1):121-35

Ultrastructural immunocytochemical evidence of the presence of a peptide related to ACTH in granules of LHRH nerve terminals in the median eminence of the guinea pig. Beauvillain JC, et al. **Cell Tissue Res** 1981; 218(1):1-6

Immunocytochemistry of luteinizing hormone-releasing hormone, vasopressin, and corticotropin following deafferentation of the basal hypothalamus of the male rat brain. Scott PM, et al. **Cell Tissue Res** 1981;219(2):393-402

Effect of escin on adrenocorticotropin and corticosterone levels in rat plasma. Hiai S, et al. **Chem Pharm Bull (Tokyo)** 1981 Feb; 29(2):490-4

Processing, turnover and release of corticotropins, endorphins and melanotropin in the toad pituitary intermediate lobe. Loh YP. **Ciba Found Symp** 1981;(81):55-78

Comparison of rat anterior and intermediate pituitary in tissue culture: corticotropin (ACTH) and beta-endorphin. Mains RE, et al. **Ciba Found Symp** 1981;(81):32-54

Effects of neonatal ACTH4-10 administration on adult adaptive behavior and brain tyrosine hydroxylase activity. Nyakas C, et al. **Dev Neurosci** 1981;4(3):225-32

Characteristics of the alpha-adrenergic stimulation of adrenocorticotropin secretion in rat anterior pituitary cells. Giguere V, et al. **Endocrinology** 1981 Sep;109(3):757-62

The influence of exogenous ACTH on the levels of corticosterone and cortisol in the plasma of young chicks (Gallus domesticus). Kalliecharan R. **Gen Comp Endocrinol** 1981 Jun;44(2):249-51

Circadian and ultradian variations of ACTH and cortisol secretion. Désir D, et al. **Horm Res** 1980;13(4-5):302-16

The biologic activity of mast cell granules in rat skin: effects of adrenocorticosteroids on late-phase inflammatory responses induced by mast cell granules. Oertel H, et al. **J Allergy Clin Immunol** 1981 Sep; 68(3):238-45

Subcellular fractionation studies on the post-translational processing of pro-adrenocorticotropic hormone/endorphin in rat intermediate pituitary. Glembotski CC. **J Biol Chem** 1981 Jul 25;256(14):7433-9

Long-term treatment of rats with morphine reduces the activity of messenger ribonucleic acid coding for the beta-endorphin/ACTH precursor in the intermediate pituitary. Höllt V, et al. **J Neurochem** 1981 Sep;37(3):619-26

Peptide hormone degradation by a rat mast cell chymase-heparin complex. Jahnke GD, et al. **Life Sci** 1981 Jul 27;29(4):397-403

Parallel stimulation of ACTH, beta-LPH + beta-endorphin and alpha-MSH release by alpha-adrenergic agents in rat anterior pituitary cells in culture. Raymond V, et al. **Mol Cell Endocrinol** 1981 Jun; 22(3):295-303

Reciprocal antagonism between ACTH1-24 and beta-endorphin in rats. Fratta W, et al. **Neurosci Lett** 1981 Jun 12;24(1):71-4

Hypothalamic multiunit activity correlates of the adrenocortical response to stress. Ramade F, et al. **Neurosci Lett** 1981 May 29;23(3):297-302

Muscarinic cholinergic influences on ACTH and beta-endorphin release mechanisms in human subjects. Risch SC, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:95-7

Localization and opiate receptor binding of enkephalin, CCK and ACTH/beta-endorphin in the rat central nervous system. Stengaard-Pedersen K, et al. **Peptides (Fayetteville)** 1981; 2 Suppl 1:3-19 (53 ref.)

ACTH-induced excessive grooming in the rat. Gispen WH, et al. **Pharmacol Ther [B]** 1981;12(1):209-46 (152 ref.)

Corticosteroidogenesis in vitro: effects of parathyroid hormone, ACTH, and calcium. Carsia RV, et al. **Proc Soc Exp Biol Med** 1981 Jul; 167(3):402-6

Characterization of a 41-residue ovine hypothalamic peptide that stimulates secretion of corticotropin and beta-endorphin. Vale W, et al. **Science** 1981 Sep 18;213(4514):1394-7

Enzymatic changes in rat thymus after intraperitoneal injections of adrenocorticotrophic hormone and corticosterone. Deschaux P, et al. **Thymus** 1981 Apr;2(6):299-304

[Biological and immunological activity similar to digitalis glycosides of synthetic ACTH and some sex hormone 14-hydroxyderivatives (author's transl)] Schreiber V, et al. **Cas Lek Cesk** 1981 May 21; 120(20):616-8 (Eng. Abstr.) (Cze)

[Hypothalamic control of ACTH secretion] Oliver C, et al. **Horm Res** 1980;13(4-5):230-41 (Eng. Abstr.) (Fre)

[ACTH measurement in the hypophysis after adrenalectomy and adrenal

cortex hormone therapy by means of microphotometry and radioimmunoassay method (author's transl)] Lange F. **Microsc Acta** 1981 Jul;84(4):329–37 (Eng. Abstr.) (Ger)
[ACTH, endorphins and related peptides (author's transl)] Imura H, et al. **Tanpakushitsu Kakusan Koso** 1981 Feb;26(2):90–101 (56 ref.) (Jpn)

CORTICOTROPIN RELEASING HORMONE

A different distribution of corticotropin releasing factor and arginine vasopressin contents in the hypothalamic nuclei after estrogen administration. Hashimoto K, et al. **Acta Med Okayama** 1981 Feb; 35(1):37–43
Characterization of corticotropin releasing factor (CRF) and arginine vasopressin in median eminence extracts on sephadex gel-filtration. Hashimoto K, et al. **Endocrinol Jpn** 1981 Feb;28(1):1–7
Corticotropin-releasing factors (CRF) secreted by the rat median eminence in vitro in the presence or absence of ascorbic acid: quantitative role of vasopressin and catecholamines. Bény JL, et al. **Endocrinology** 1981 Sep;109(3):813–7
Dynamics of the formation and release of corticotrophin releasing activity by the rat hypothalamus in vitro. Gillham B, et al. **J Endocrinol** 1981 Aug;90(2):201–10
Studies on the corticotrophin releasing activity of a posterior pituitary extract. Kirkland SC, et al. **J Endocrinol** 1981 Jun;89(3):423–9
Characterization of corticotropin-releasing factor activity from sheep hypothalamic extracts. Jutisz M, et al. **Life Sci** 1981 Jun 15; 28(24):2761–8
Characterization of a 41-residue ovine hypothalamic peptide that stimulates secretion of corticotropin and beta-endorphin. Vale W, et al. **Science** 1981 Sep 18;213(4514):1394–7

CROSS-CULTURAL COMPARISON

[Treatment of schizophrenic patients with clomacran. A transcultural study (author's transl)] Torres Ruiz A, et al. **Arch Neurobiol (Madr)** 1981 Mar-Apr;44(2):117–24 (Eng. Abstr.) (Spa)

CROWDING

Cageing density and dopamine striatal elimination after amphetamine in the rat. Lokiec F, et al. **Psychopharmacology (Berlin)** 1981; 73(4):402–3

DANSYL COMPOUNDS

Hapten-induced changes in pig anti-dansyl antibodies revealed by EPR spectra of spin-labelled antibodies. Käiväräinen AI, et al. **Immunol Lett** 1981 Apr;3(1):5–11

DEPRESSION

Drug treatment of depression in children. Pearce JB. **Acta Paedopsychiatr (Basel)** 1981 Feb;46(5–6):317–28
An experimental study of the clinical judgment of general physicians in evaluating and prescribing for depression. Fisch HU, et al. **Br J Psychiatry** 1981 Feb;138:100–9
Current antidepressant drugs: their clinical use. Hollister LE. **Drugs** 1981 Aug;22(2):129–52 (93 ref.)
Effects of antidepressants in the rat forced swimming test. Kitada Y, et al. **Eur J Pharmacol** 1981 Jun 19;72(2–3):145–52
The significance of secondary depression. Clayton PJ, et al. **J Affective Disord** 1981 Mar;3(1):25–35
Relevance of tryptophan and tyrosine availability in endogenous and 'non-endogenous' depressives treated with imipramine or clomipramine. Møller SE, et al. **J Affective Disord** 1981 Sep;3(3):231–44
Differential effects of cognitive therapy and pharmacotherapy on depressive symptoms. Rush AJ, et al. **J Affective Disord** 1981 Sep; 3(3):221–9
Multicentre depression [editorial] **Lancet** 1981 Sep 12;2(8246):563–4
Amitriptyline and scopolamine in an animal model of depression. Katz RJ, et al. **Neurosci Biobehav Rev** 1981 Summer;5(2):265–71
Amphetamine and tranylcypromine in an animal model of depression: pharmacological specificity of the reversal effect. Katz RJ, et al. **Neurosci Biobehav Rev** 1981 Summer;5(2):259–64
Animal model of depression: effects of electroconvulsive shock therapy. Katz RJ. **Neurosci Biobehav Rev** 1981 Summer;5(2):273–7
Further studies on a novel animal model of depression: therapeutic effects of a tricyclic antidepressant. Roth KA, et al. **Neurosci Biobehav Rev** 1981 Summer;5(2):253–8
The effect of antidepressants on behavioral despair in rats. Górka Z, et al. **Pol J Pharmacol Pharm** 1980 Jul–Aug;32(4):463–8
Flupenthixol versus combined fluphenazine-nortriptyline in depressive illness. Conway JF. **Practitioner** 1981 Mar;225(1353):400–4
[The treatment of an anxiety - depression syndrome in young women. Report of a case (author's transl)] Leyne P. **Sem Hop Paris** 1981 Jun 18–25;57(25–28):1226–7 (Eng. Abstr.) (Fre)
[Urinary excretion of MHPG in endogenous depression. Clinico-therapeutic index] Roccatagliata G, et al. **Minerva Psichiat** 1981 Apr–Jun;22(2):75–8 (Eng. Abstr.) (Ita
[A diagram illustrating experimental evaluation of psychotropic drug (author's transl)] Brzeziński J. **Psychiatr Pol** 1981 Jan–Feb; 15(1):37–47 (Eng. Abstr.) (Pol
[Changes in the levels of adrenergic and serotoninergic indices in patien with depressive states] Misionzhnik EIu, et al. **Zh Nevropatol Psikhiatr** 1981;81(4):543–51 (Eng. Abstr.) (Rus

DEPRESSIVE DISORDER

The polysymptomatic melancholic as patient in the internist's office. Ros BE. **Acta Med Scand** 1981;209(6):433–6
Drug treatment of depression in children. Pearce JB. **Acta Paedopsychiatr (Basel)** 1981 Feb;46(5–6):317–28
TSH, HGH, HPr, and cortisol response to TRH in depressed patien Ramseier F, et al. **Acta Psychiatr Belg** 1980 Jul–Aug;80(4):399–409
Changes in the electrocardiogram during treatment with tricyclic antidepressant drugs in endogenous depression. Bilikiewicz A, et al **Agressologie** 1979;20(D):287–9
Peripheral metabolism of indoleamines and catecholamines in endogenou depressive syndrome. Puzynski S, et al. **Agressologie** 1979; 20(D):245–51
Clinical experience with some beta blocking agents and their derivatives in endogenous depressions. Svestka J, et al. **Agressologie** 1979; 20(D):295–8
CSF GABA in normal subjects and patients with depressio schizophrenia, mania, and anorexia nervosa. Gerner RH, et al. **Am J Psychiatry** 1981 Aug;138(8):1098–101
Cognitive dysfunction and imipramine in outpatient depressive. Glass RM, et al. **Arch Gen Psychiatry** 1981 Sep;38(9):1048–51
Lithium carbonate in the treatment of acute depressive illness. Khan MC **Bibl Psychiatr** 1981;(161):244–8
Memory performances in depressed patients during prophylactic treatme with lithium salts. Zerbi F, et al. **Bibl Psychiatr** 1981;(161):190–6
Blood platelets and psychiatry. Campbell IC. **Br J Psychiatry** 1981 Jan; 138:78–80
A pilot study of the mechanism of action of desipramine. Checkley SA, et al. **Br J Psychiatry** 1981 Mar;138:248–51
Lithium induces rapid relief of depression in tricyclic antidepressant drug non-responders. Dé Montigny C, et al. **Br J Psychiatry** 1981 Mar; 138:252–6
Constructs and 'conflict' in depression. Sheehan MJ. **Br J Psychol** 1981 May;72(Pt 2):197–209
The new psychiatry [editorial] **Br Med J [Clin Res]** 1981 Aug 22; 283(6290):513–4
Psychodynamic aspects in the use of monoamine oxidase inhibito antidepressants. Roskos SR, et al. **Bull Menninger Clin** 1981 Mar; 45(2):143–8
Elderly depressives: treatment and follow-up. Gordon WF. **Can J Psychiatry** 1981 Mar;26(2):110–3
Pharmacokinetics and efficacy of maprotiline and amitriptyline i endogenous depression: a double-blind controlled trial. Montgomery SA, et al. **Clin Ther** 1980;3(4):292–310
Comparison of midday serum dopamine-beta-hydroxylase activity i depressed patients and normal controls. Nasr S, et al. **Commun Psychopharmacol** 1980;4(4):263–7
Trazodone: a review of its pharmacological properties and therapeutic use in depression and anxiety. Brogden RN, et al. **Drugs** 1981 Jun; 21(6):401–29 (156 ref.)
Current antidepressant drugs: their clinical use. Hollister LE. **Drugs** 1981 Aug;22(2):129–52 (93 ref.)
Multicentre study with viloxazine (Vivalan) in depressed patients. Kabe J, et al. **Int Pharmacopsychiatry** 1980;15(4):228–39
A double-blind multicentre trial comparing the efficacy and side-effects of mianserin and chlorimipramine in depressed in- and outpatients. Pinder RM, et al. **Int Pharmacopsychiatry** 1980;15(4):218–27
Trazodone in depression. Wheatley D. **Int Pharmacopsychiatry** 1980; 15(4):240–6
Cerebrospinal fluid amine metabolites, tryptophan and clinical parameters in depression. Part 1. Background variables. Banki CM, et al. **J Affective Disord** 1981 Jun;3(2):81–9
Relevance of tryptophan and tyrosine availability in endogenous an 'non-endogenous' depressives treated with imipramine or clomipram Møller SE, et al. **J Affective Disord** 1981 Sep;3(3):231–44
The activity of the lithium—sodium countertransport system i erythrocytes in depression and mania. Rybakowski J, et al. **J Affective Disord** 1981 Mar;3(1):59–64
Comparison of molindone and tranylcypromine in the treatment o refractory depression. Small JG, et al. **J Clin Pharmacol** 1981 Aug-Sep; 21(8–9):351–8
Refractory depression: prediction of non-response by clinical indicators. Kupfer DJ, et al. **J Clin Psychiatry** 1981 Aug;42(8):307–12
Amoxapine: once versus divided daily doses in neurotic and endogeno depression. Ragheb M, et al. **J Clin Psychiatry** 1981 Aug; 42(8):318–21
CSF-MHPG in depressive syndromes: basal values and

imipramine-induced modifications. Roccatagliata G, et al. **Neuropsychobiology** 1981;7(4):169–71

Animal models and human depressive disorders. Katz RJ. **Neurosci Biobehav Rev** 1981 Summer;5(2):231–46 (243 ref.)

Influence of unilateral ECT on tryptophan metabolism in endogenous depression. Smith DF, et al. **Pharmacopsychiatria** 1981 Jul; 14(4):135–8

Management of depressive neurosis. Shaw SH. **Practitioner** 1981 Feb; 225(1352):228–30

Decreased tryptophan availability in endogenous depression caused by disturbed plasma leucine clearance. Møller SE, et al. **Prog Neuropsychopharmacol** 1981;5(3):277–9

Electroconvulsive therapy in the medically ill patient. Bidder TG. **Psychiatr Clin North Am** 1981 Aug;4(2):391–405 (60 ref.)

Depression in the medically ill. Klerman GL. **Psychiatr Clin North Am** 1981 Aug;4(2):301–17

Effect of carbamazepine on CSF opioid activity; relationship to antidepressant response. Post RM, et al. **Psychiatry Res** 1981 Aug; 5(1):59–66

Relationship between urinary free cortisol and CSF opioid binding activity in depressed patients and normal volunteers. Rubinow DR, et al. **Psychiatry Res** 1981 Aug;5(1):87–93

Treatment validity of different diagnostic concepts of depression. Zisook S, et al. **Psychiatry Res** 1981 Aug;5(1):77–85

Continuation therapy with lithium and amitriptyline in unipolar depressive illness: a controlled clinical trial. A report by the Medical Research Council Drug Trials Subcommittee. **Psychol Med** 1981 May; 11(2):409–16

Monoamine oxidase inhibitor efficacy in depression and the 'cheese effect'. Sandler M. **Psychol Med** 1981 Aug;11(3):455–8

[Results of the clinical trial with nomifensine (author's transl)] Kabeš J, et al. **Cesk Psychiatr** 1981 Feb;77(1):42–9 (Eng. Abstr.) (Cze)

[Third-generation antidepressive agents. Experience with 100 cases of primary depression treated with viloxazine, nomifensine and mianserin] Faravelli C, et al. **Minerva Psichiatr** 1981 Apr–Jun;22(2):79–83 (Eng. Abstr.) (Ita)

[Clinical experience with treatment of depressions by nomiphenzine (author's transl)] Pogády J, et al. **Cesk Psychiatr** 1981 Feb; 77(1):11–6 (Eng. Abstr.) (Slo)

DESIPRAMINE

Concentrations of desipramine in elderly women. Cutler NR, et al. **Am J Psychiatry** 1981 Sep;138(9):1235–7

A pilot study of the mechanism of action of desipramine. Checkley SA, et al. **Br J Psychiatry** 1981 Mar;138:248–51

Plasma concentration monitoring of hydroxylated metabolites of imipramine and desipramine. DeVane CL, et al. **Drug Intell Clin Pharm** 1981 Apr;15(4):263–6

Interaction of desipramine and amitriptyline with adrenergic mechanisms in the human iris in vivo. Szabadi E, et al. **Eur J Clin Pharmacol** 1981; 19(6):403–8

High-affinity [3H] DMI binding is associated with neuronal noradrenaline uptake in the periphery and the central nervous system. Langer SZ, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):423–4

Simultaneous determination of imipramine, desipramine, and their 2-hydroxy metabolites in plasma by ion-pair reversed-phase high-performance liquid chromatography with amperometric detection. Suckow RF, et al. **J Pharm Sci** 1981 Mar;70(3):257–61

Pre- and postsynaptic adrenergic activation by norepinephrine reuptake inhibitors in the field-stimulated rat vas deferens. Lotti VJ, et al. **Life Sci** 1981 Aug 10;29(6):633–9

Prediction of steady state plasma and saliva levels of desmethylimipramine using a single dose, single time point procedure. Cooper TB, et al. **Psychopharmacology (Berlin)** 1981;74(2):115–21

Supersensitivity to L-5-hydroxytryptophan after 5,7-dihydroxytryptamine injections in desmethylimipramine- and nomifensine-pretreated rats: behavioral evidence for postsynaptic supersensitivity. Ortmann R, et al. **Psychopharmacology (Berlin)** 1981; 74(2):109–14

DESOXYCORTICOSTERONE

Effect of cortisol, deoxycorticosterone and 19-nortestosterone on the gametogenesis of the snail Helix pomatia. Csaba G, et al. **Acta Biol Acad Sci Hung** 1981;32(1):15–8

Inner medullary osmolality and sodium concentration are decreased in rats during escape from DOCA-induced salt retention. Düsing R, et al. **Clin Sci** 1981 Apr;60(4):467–9

Effects of sodium loading, desoxycorticosterone acetate, and corticosterone on urinary kallikrein excretion. Bönner G, et al. **Horm Res** 1981;14(2):87–94

A simultaneous radioimmunoassay for aldosterone and its precursors: human plasma levels following the inhibition of converting enzyme, before and after blockade of prostaglandin biosynthesis. Witzgall H, et al. **J Clin Chem Clin Biochem** 1981 Jun;19(6):387–94

[Histochemical localization of Na+, K+-ATPase in rat submandibular gland. The effects of mineralocorticoid and sodium ion (author's transl)] Kida T, et al. **Josai Shika Daigaku Kiyo** 1980;(9):155–8 (Eng. Abstr.) (Jpn)

DEXTROAMPHETAMINE

Amphetamine behavioral toxicity: rotational behavior after chronic intrastriatal infusion. Dougherty GG Jr, et al. **Biol Psychiatry** 1981 May; 16(5):479–88

Disrupted latent inhibition in the rat with chronic amphetamine or haloperidol-induced supersensitivity: relationship to schizophrenic attention disorder. Solomon PR, et al. **Biol Psychiatry** 1981 Jun; 16(6):519–37

The acquisition of responding with conditioned reinforcement: effects of cocaine, (+)-amphetamine and pipradrol. Beninger RJ, et al. **Br J Pharmacol** 1981 Sep;74(1):149–54

Cocaine cue in pigeons: time course studies and generalization to structurally related compounds (norcocaine, WIN 35,428 and 35,065-2) and (+)-amphetamine. Järbe TU. **Br J Pharmacol** 1981 Aug; 73(4):843–52

Differential effects of estrogen and androgen on locomotor activity induced in castrated male rats by amphetamine, a novel environment, or apomorphine. Menniti FS, et al. **Brain Res** 1981 Jul 6; 216(1):89–107

Detailed analysis of the effects of apomorphine and d-amphetamine on spontaneous locomotor behaviour of rats as measured in a TV-based, automated open-field system. Nickolson VJ. **Eur J Pharmacol** 1981 Jun 10;72(1):45–56

The regional distribution of d-amphetamine and local glucose utilization in rat brain during continuous amphetamine administration. Eison MS, et al. **Exp Brain Res** 1981;43(3–4):281–8

Application of chiral lanthanide nuclear magnetic resonance shift reagents to pharmaceutical analysis. II. Determination of dextro- and levoamphetamine mixtures. Wainer IW, et al. **J Assoc Off Anal Chem** 1981 Jul;64(4):848–50

Neuronal responses of the globus pallidus to systemic administration of d-amphetamine: investigation of the involvement of dopamine, norepinephrine, and serotonin. Bergstrom DA, et al. **J Neurosci** 1981 Mar;1(3):292–9

Behavioral and neurochemical interactions of dextroamphetamine and methylphenidate in rats. Reigle TG, et al. **J Pharm Sci** 1981 Jul; 70(7):816–8

3H-amphetamine concentrations in the brains of young and aged rats: implications for assessment of drug effects in aged animals. Truex LL, et al. **Neurobiol Aging** 1980 Summer;1(1):93–5

Effects of chronic amphetamine treatment on the glutamate concentration in cerebrospinal fluid and brain: implications for a theory of schizophrenia. Kim JS, et al. **Neurosci Lett** 1981 Jun 12;24(1):93–6

Post-amphetamine depression of self-stimulation behavior in rats: prophylactic effects of lithium. Predy PA, et al. **Neurosci Lett** 1981

May 29;23(3):343–7

Acute amphetamine response predicts antidepressant and antipsychotic responses to lithium carbonate in schizophrenic patients. van Kammen DP, et al. **Psychiatry Res** 1981 Jun;4(3):313–25

Self-stimulation and amphetamine: tolerance to d and l isomers and cross tolerance to cocaine and methylphenidate. Leith NJ, et al. **Psychopharmacology (Berlin)** 1981;74(1):23–8

Cageing density and dopamine striatal elimination after amphetamine in the rat. Lokiec F, et al. **Psychopharmacology (Berlin)** 1981; 73(4):402–3

Effect of chronic amphetamine administration on central dopaminergic mechanisms in the vervet. Owen F, et al. **Psychopharmacology (Berlin)** 1981;74(3):213–6

DIAZEPAM

Alterations in human memory following acute maprotiline, diazepam and codeine administration. Liljequist R, et al. **Acta Pharmacol Toxicol (Copenh)** 1981 Feb;48(2):190–2

Effect of gamma-vinyl GABA alone or associated with diazepam on a conflict test in the rat. Huot S, et al. **Adv Biochem Psychopharmacol** 1981;29:45–52

Promotion of intramuscular diazepam questioned [letter] Watson DM, et al. **Am J Hosp Pharm** 1981 Jul;38(7):968, 970–1

Hazards of mistaking haloperidol for diazepam [letter] Nininger JE, et al. **Am J Psychiatry** 1981 Aug;138(8):1130

Effect of propranolol on circulatory responses to induction of diazepam-nitrous oxide anesthesia and to endotracheal intubation. McCammon RL, et al. **Anesth Analg (Cleve)** 1981 Aug;60(8):579–83

Interaction of depressant, convulsant, and anticonvulsant barbiturates with the [3H]diazepam binding site of the benzodiazepine-GABA-receptor-ionophore complex. Ticku MK. **Biochem Pharmacol** 1981 Jun 15;30(12):1573–9

Clinical evaluation of diazepam for relief of postoperative pain. Singh PN, et al. **Br J Anaesth** 1981 Aug;53(8):831–6

Effects of phenytoin on [3H]diazepam binding in dissociated primary cortical cell culture. Gallager DW, et al. **Brain Res** 1981 Aug 10; 218(1–2):319–30

Ethyl beta-carboline-3-carboxylate antagonizes the action of GABA and benzodiazepines in the hippocampus. Polc P, et al. **Brain Res** 1981 Jul 27;217(1):216–20

Diazepam binding of dissociated hippocampal cultures from fetal mice. Walker CR, et al. **Brain Res** 1981 Jul;227(4):565–78

Benzodiazepine binding and interactions with the GABA receptor complex in living cultures of rat cerebral cortex. White WF, et al. **Brain Res** 1981 Jun 29;215(1–2):162–76

Effects of diazepam on body temperature of the aged squirrel monkey. Clark SM, et al. **Brain Res Bull** 1981 Jul;7(1):5–9

Estimation of diazepam adsorbed on glass surfaces and silicone-coated surfaces as models of surfaces of containers. Mizutani T, et al. **Chem Pharm Bull (Tokyo)** 1981 Apr;29(4):1182–3

Promethazine and diazepam potentiate the haloperidol induced prolactin responses. Arató M. **Commun Psychopharmacol** 1980;4(4):317–22

Drug-specific EEG frequency spectra and their time courses produced in the cat by antidepressants and a benzodiazepine. Fairchild MD, et al. **Electroencephalogr Clin Neurophysiol** 1981 Jul;52(1):81–8

3-hydroxymethyl-beta-carboline antagonizes some pharmacologic actions of diazepam. Skolinick P, et al. **Eur J Pharmacol** 1981 Feb 19; 69(4):525–7

Comparative protein binding of diazepam and desmethyldiazepam. Allen MD, et al. **J Clin Pharmacol** 1981 May–Jun;21(5–6):219–23

Multicenter double-blind efficacy and safety study comparing alprazolam, diazepam and placebo in clinically anxious patients. Cohn JB. **J Clin Psychiatry** 1981 Sep;42(9):347–51

Altered drug binding to serum proteins in pregnant women: therapeutic relevance. Perucca E, et al. **J R Soc Med** 1981 Jun;74(6):422–6

Norharman inhibition of [3H]diazepam binding in mouse brain. Morin AM, et al. **Life Sci** 1981 May 18;28(20):2257–63

Diazepam and driving ability. Landauer AA. **Med J Aust** 1981 Jun 13; 1(12):624–6

Pentobarbital enhances [3H]diazepam binding to soluble receptors at the benzodiazepine--GABA-receptor-ionophore complex. Davis WC, et al. **Neurosci Lett** 1981 May 6;23(2):209–13

Fibre-optic gastroscopy and intravenous diazepam: their combined effect on arterial oxygen saturation. Harrison RN, et al. **Pharmatherapeutica** 1981;2(9):565–7

Effect of chloro-N-desmethyldiazepam on serum and brain tryptophan and serotonin in relation to the activity of central serotonergic neurons. Valzelli L, et al. **Pol J Pharmacol Pharm** 1981 Jan–Feb;33(1):37–42

A multicenter controlled trial in phobic-obsessive psychoneurosis. The effect of chlorimipramine and of its combinations with haloperidol and diazepam. Cassano GB, et al. **Prog Neuropsychopharmacol** 1981; 5(2):129–38

Effects of diazepam on operant behavior in man. Carlton PL, et al. **Psychopharmacology (Berlin)** 1981;73(4):314–7

Psychomotor performance and real driving performance of outpatients receiving diazepam. de Gier JJ, et al. **Psychopharmacology (Berlin)** 1981; 73(4):340–4

The effect of chronic diazepam treatment on discrimination performance and 3H-flunitrazepam binding in the brains of shocked and nonshocked rats. Grimm VE, et al. **Psychopharmacology (Berlin)** 1981; 74(2):132–6

Pre-exposure effects of morphine, diazepam and delta 9-THC on the formation of conditioned taste aversions. Switzman L, et al. **Psychopharmacology (Berlin)** 1981;74(2):149–57

Diazepam-cimetidine drug interaction: a clinically significant effect. Ruffalo RL, et al. **South Med J** 1981 Sep;74(9):1075–8 (20 ref.)

Diazepam-induced neural tube closure defects in explanted early chick embryos. Nagele RG, et al. **Teratology** 1981 Jun;23(3):343–9

The effect of diazepam on meiosis in the CF-1 mouse. Stenchever MA, et al. **Teratology** 1981 Apr;23(2):279–81

[Interrelationship of the tranquilizers diazepam and lonetil with dopamine mediation in the central nervous system] Ovcharov R, et al. **Eksp Med Morfol** 1981;20(2):88–96 (Eng. Abstr.) (Bul)

[Diazepam levels in the ventricular cerebrospinal fluid and peripheral venous blood in man] Boulard G, et al. **Ann Anesthesiol Fr** 1981; 22(2):185–90 (Eng. Abstr.) (Fre)

[Comparative pharmacokinetics of diazepam and flunitrazepam] Cano JP, et al. **Ann Anesthesiol Fr** 1981;22(2):175–9 (Eng. Abstr.) (Fre)

[Physico-chemical study of diazepam and hydrophilic excipients interaction (author's transl)] Neamtu M, et al. **Ann Pharm Fr** 1980; 38(6):507–11 (Eng. Abstr.) (Fre)

[Clinical pharmacokinetics of midazolam, flunitrazepam and diazepam (author's transl)] Lauven PM, et al. **Anaesth Intensivther Notfallmed** 1981 Jun;16(3):135–42 (Eng. Abstr.) (Ger)

[Plasma levels following high diazepam doses in intensive-care medicine (author's transl)] Ochs HR. **Anaesth Intensivther Notfallmed** 1981 Jun; 16(3):143–4 (Eng. Abstr.) (Ger)

[A floating capsule with slow release of drugs: a new method of oral drug medication (author's transl)] Müller-Lissner SA, et al. **Dtsch Med Wochenschr** 1981 Sep 4;106(36):1143–7 (Eng. Abstr.) (Ger)

[Effects of diazepam and thiamylal on reticular multi-unit activity, visual evoked responses, EEG and arterial blood pressure in rabbits (author's transl)] Ueda Y. **Nippon Geka Hokan** 1980 Sep 1;49(5):595–607 (Eng. Abstr.) (Jpn)

[Effect of GABA-negative preparations on the anxiolytic and sedative effects of diazepam] Andreev BV, et al. **Biull Eksp Biol Med** 1981 Jun; 91(6):685–7 (Eng. Abstr.) (Rus)

DIBENZAZEPINES

Differential actions of mianserin and iprindole on the sensitivity of cortical neurons to noradrenaline: effect of chronic treatment. Olpe HR, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):381–5

A double-blind multicentre trial comparing the efficacy and side-effects of mianserin and chlorimipramine in depressed in- and outpatients. Pinder RM, et al. **Int Pharmacopsychiatry** 1980;15(4):218–27

Clozapine inhibition of metenkephalin binding to synaptosome-enriched fractions of rat whole brain and hippocampus. Somoza E, et al. **Neurochem Res** 1981 Apr;6(4):413–24

The effect of imipramine and mianserin on the behavior and EEG afterdischarges induced by single electric stimulation of the rabbit amygdala. Ossowska K, et al. **Pol J Pharmacol Pharm** 1980 Jul–Aug; 32(4):513–22

Differences in presynaptic alpha-blockade, noradrenaline uptake inhibition, and potential antidepressant activity between (+)- and (-)mianserin. Schoemaker H, et al. **Psychopharmacology (Berlin)** 1981; 74(2):137–42

[Noveril in depression] Medvecký J, et al. **Agressologie** 1979; 20(D):311–2 (Eng. Abstr.) (Ger)

[Noveril in high doses in the treatment of depression] Molcan J, et al. **Agressologie** 1979;20(D):307–9 (Eng. Abstr.) (Ger)

[Hemoperfusion and forced diuresis in dibenzepine poisoning (letter)] Vlachoyannis J, et al. **Dtsch Med Wochenschr** 1981 Oct 2; 106(40):1314–5 (Ger)

[Alkylation of 6-benzyl-5H-dibenzo(d,f)-(1,3)diazepine] Boido A, et al. **Boll Soc Ital Biol Sper** 1981 Apr 15;57(7):759–65 (Eng. Abstr.) (Ita)

[Third-generation antidepressive agents. Experience with 100 cases of primary depression treated with viloxazine, nomifensine and mianserin] Faravelli C, et al. **Minerva Psichiatr** 1981 Apr–Jun;22(2):79–83 (Eng. Abstr.) (Ita)

[The most common complications in neuroleptic therapy. A case report] Preradović M. **Vojnosanit Pregl** 1981 May–Jun;38(3):211–2 (Ser)

DIBENZOTHIEPINS

Further clinical experiences with optical isomers of the L and D clorothepin. Náhunek K, et al. **Agressologie** 1979;20(D):275–8

Reduction of octoclothepine-N-oxide by rat liver microsomes. Helia O, et al. **Eur J Drug Metab Pharmacokinet** 1981;6(2):155–8

Effects of microinjection of 2-chloro-11 (2-dimethylaminoethoxy)-dibenzo[b,f]-thiepine (zotepine), thioridazine and haloperidol into the striatum and nucleus accumbens on stereotypic

behaviour and motor activity. Lai H, et al. **J Pharm Pharmacol** 1981 Apr;33(4):252-4
[Effects of the intraventricular injection of methiothepin and methergoline on the sleep of rats] Laguzzi R. **C R Soc Biol (Paris)** 1981; 175(2):160-3 (Eng. Abstr.) **(Fre)**

DIBENZOXAZEPINES

Physostigmine in amoxapine overdose [letter] Ross SR, et al. **Am J Hosp Pharm** 1981 Aug;38(8):1121-2
Very high dose loxapine in refractory schizophrenic patients. Lehmann CR, et al. **Am J Psychiatry** 1981 Sep;138(9):1212-4
Acutely ill schizophrenic patients treated with loxapine. A clinical study in a community mental health center. Rasul M. **Clin Ther** 1980; 3(4):242-9
Amoxapine: once versus divided daily doses in neurotic and endogenous depression. Ragheb M, et al. **J Clin Psychiatry** 1981 Aug; 42(8):318-21
The effects of amoxapine and ethanol on psychomotor skills related to driving: a placebo and standard controlled study. Wilson WH, et al. **Prog Neuropsychopharmacol** 1981;5(3):263-70
Treatment validity of different diagnostic concepts of depression. Zisook S, et al. **Psychiatry Res** 1981 Aug;5(1):77-85

DIIODOTYROSINE

Experimental study of hormone receptor development in a unicellular model system. Csaba G, et al. **Exp Cell Biol** 1981;49(3):173-6

DISCRIMINATION LEARNING

Changes in brain biogenic amines in cats performing a symmetrically reinforced go-nogo visual discrimination task. Kitsikis A, et al. **Behav Neural Biol** 1981 Jun;32(2):133-47
Effects of pentobarbital on delayed alternation performance. Terry WS, et al. **Behav Neural Biol** 1981 Jul;32(3):380-5
Age and neurochemical correlates of radial maze performance in rats. Ingram DK, et al. **Neurobiol Aging** 1981 Spring;2(1):41-7

DOPA

Rapid and simple analysis of DOPA and 5-HTP using high performance liquid chromatography with electrochemical detection. Arnerić SP, et al. **Brain Res Bull** 1981 May;6(5):407-11
Monoamine precursor uptake in ganglia of a mollusc Anodonta cygnea L. (Bivalvia) An autoradiographic and ultrastructural study. Elekes K. **Cell Tissue Res** 1981;219(2):403-15
Endogenous dopa in rat brain. Occurrence, distribution and relationship to changes i catecholamine synthesis. Thiede HM, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jul;316(4):299-303
[Interaction of dihydroxyphenylalanine with the acid proteins of rat brain chromatin] Tret'iak TM, et al. **Dokl Akad Nauk SSSR** 1981; 257(5):1262-4 **(Rus)**

DOPAMINE

Interaction at the synaptic level of fusaric acid with neurotransmitters. Fischer HD, et al. **Acta Biol Med Ger** 1980;39(8-9):935-40
Further studies of the chemical sensitivity of the oscillatory potentials of the electroretinogram (ERG). II. Glutamate-aspartate-and dopamine antagonists. Wachtmeister L. **Acta Ophthalmol (Copenh)** 1981 Apr; 59(2):247-58
Density of amine accumulating neurons in rabbit and guinea-pig retina. Ehinger B, et al. **Acta Physiol Scand** 1981 May;112(1):111-2
Dopamine uptake in platelets: two different low-affinity, saturable mechanisms. Lingjaerde O, et al. **Agents Actions** 1981 Jul; 11(4):410-6
A functional analysis of dopaminergic innervation of the neurohypophysis. Passo SS, et al. **Am J Physiol** 1981 Sep;241(3):E186-90
Reverse-phase high-performance liquid chromatographic separation and electrochemical detection of norepinephrine, dopamine, serotonin, and related major metabolites. Kempf E, et al. **Anal Biochem** 1981 Apr; 112(2):223-31
Application of high-performance liquid chromatography with a chemiluminescence detection system to determine catecholamines in urine. Kobayashi S, et al. **Anal Biochem** 1981 Mar 15;112(1):99-104
Effect of neonatal administrations of 6-OHDA on the brain development. I. Alteration in the striatum. Imamoto K, et al. **Arch Histol Jpn** 1980 Oct;43(4):347-64
The influence of dopamine and dopaminergic agonists on the contractions of field stimulated rat vas deferens. György L, et al. **Arch Int Pharmacodyn Ther** 1981 Mar;250(1):55-64
An analysis of the effects of apomorphine and haloperidol on the release of [3H]-dopamine and [3H]-noradrenaline from rabbit brain slices. Kelly MJ. **Arch Int Pharmacodyn Ther** 1981 Mar;250(1):18-29
Effects of intracerebroventricular administration of dopamine and metoclopramide on blood pressure in rats. Kondo K, et al. **Arch Int Pharmacodyn Ther** 1981 Apr;250(2):273-8
Analysis of responses to dopamine in the mesenteric vascular bed of the cat. Lippton HL, et al. **Arch Int Pharmacodyn Ther** 1981 May; 251(1):136-49
Effects of dopamine and its antagonist domperidone cannot be explained by an effect on alpha 1-adrenergic receptors. Schuurkes JA, et al. **Arch Int Pharmacodyn Ther** 1981 Apr;250(2):324-7
Barrel rotation induced by vasopressin and involvement of dopaminergic and cholinergic functions in rats. Yamada K, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):88-94
Striatal dopamine turnover and L-dopa treatment after short-term exposure of rats to manganese. Shukla GS, et al. **Arch Toxicol** 1981 Jun;47(3):191-6
High-affinity stereospecific binding of 3H-dopamine in rat brain: interaction with endogenous dopamine. Bacopoulos NG. **Biochem Pharmacol** 1981 Jul 15;30(14):2037-40
Amfonelic acid antagonism of dopamine and norepinephrine depletion by alpha-methyl-m-tyrosine in rat brain. Fuller RW, et al. **Biochem Pharmacol** 1981 Jul 15;30(14):2025-6
Changes in plasma catecholamine concentrations during endotracheal intubation. Russell WJ, et al. **Br J Anaesth** 1981 Aug;53(8):837-9
Evidence for an inhibitory presynaptic component of neuroleptic drug action. de Belleroche JS, et al. **Br J Pharmacol** 1981 Mar; 72(3):427-33
Dopamine-like properties of ephedrine in rat brain. Zarrindast MR. **Br J Pharmacol** 1981 Sep;74(1):119-22
Positive and negative schizophrenic symptoms and the role of dopamine [letter] Ashcroft GW, et al. **Br J Psychiatry** 1981 Mar;138:268-9
Dopamine hypothesis in acute psychosis [letter] Marsden CD. **Br J Psychiatry** 1981 Mar;138:269-70
Differential effects of gonadal steroids on dopamine metabolism in mesolimbic and nigro-striatal pathways of male rat brain. Alderson LM, et al. **Brain Res** 1981 Aug 10;218(1-2):189-206
Modulation of slow postsynaptic potentials by dopamine, in rabbit sympathetic ganglion. Ashe JH, et al. **Brain Res** 1981 Jul 27; 217(1):93-106
Mesocortical dopamine neurons: rapid transmitter turnover compared to other brain catecholamine systems. Bannon MJ, et al. **Brain Res** 1981 Aug 10;218(1-2):376-82
The response of individual sympathetic preganglionic neurones to microelectrophoretically applied endogenous monoamines. Coote JH, et al. **Brain Res** 1981 Jun 29;215(1-2):135-45
Release of endogenous catecholamines from slices of hypothalamus of rats. Hamlet MA, et al. **Brain Res** 1981 Aug 3;217(2):315-25
Opposite changes in dopamine utilization in the nucleus accumbens and the frontal cortex after electrolytic lesion of the median raphe in the rat. Herve D, et al. **Brain Res** 1981 Jul 20;216(2):422-8
Puberty of female rats may in part be explained by decreased hypothalamic dopamine receptor sensitivity. Lamberts R, et al. **Brain Res** 1981 Jun 29;215(1-2):375-81
Release of somatostatin from extra-hypothalamic rat brain slices: inhibition by dopamine and morphine. Lee CM, et al. **Brain Res** 1981 Aug 31;219(2):355-61
Chemical deafferentation of the olfactory bulb: plasticity of the levels of tyrosine hydroxylase, dopamine and norepinephrine. Nadi NS, et al. **Brain Res** 1981 Jun 1;213(2):365-77
High resolution radioautography of central dopaminergic fibers labelled in vitro with [3H]dopamine or [3H]norepinephrine. Nguyen-Legros J, et al. **Brain Res** 1981 Jun 1;213(2):265-76
Selective activation of tuberoinfundibular dopaminergic neurons in the chronically restrained rat. Seegal RF. **Brain Res** 1981 Jul 20; 216(2):460-5
Differential functional ontogeny of dopamine presynaptic receptor regulation. Shalaby IA, et al. **Brain Res** 1981 Jun;227(3):434-9
Changes in dopamine and DOPAC following systemic administration of apomorphine and 3,4-dihydroxyphenylamino-2-imidazoline (DPI) in rats. Springer J, et al. **Brain Res** 1981 Sep 7;220(1):226-30
Effects of ventral tegmental area stimulation and microiontophoretic application of dopamine and norepinephrine on hypothalamic neurons. Barone FC, et al. **Brain Res Bull** 1981 Aug;7(2):181-93
Secretion of hypothalamic dopamine into pituitary stalk blood of aged female rats. Reymond MJ, et al. **Brain Res Bull** 1981 Jul;7(1):69-73
Catecholamines and 5-hydroxytryptamine in photophores of Porichthys notatus. Radioenzymatic detection and radioautographic localization. Anctil M, et al. **Cell Tissue Res** 1981;219(3):557-66
In normal young men acute dopaminergic blockade does not impair free water excretion following a standard water load. Cohen M, et al. **Commun Psychopharmacol** 1980;4(4):323-6
Activation of adenylate cyclase in rat striatum by an ergoline dopamine agonist, pergolide. Wong DT, et al. **Commun Psychopharmacol** 1980; 4(4):269-75
Dilated fixed pupils due to administration of high doses of dopamine hydrochloride. Ong GL, et al. **Crit Care Med** 1981 Sep;9(9):658-9
3-O-methyl-alpha-methyldopamine, a urinary metabolite of p-methoxyamphetamine in dog and monkey. Hubbard JW, et al. **Drug Metab Dispos** 1981 May-Jun;9(3):250-4
Intraventricular administration of vasopressin and oxytocin effects the

steady-state levels of serotonin, dopamine and norepinephrine in rat brain. Schwarzberg H, et al. **Endocrinol Exp (Bratisl)** 1981; 15(2):75–80

Dopaminergic and serotonergic involvement in opiate-induced prolactin release in monkeys. Wehrenberg WB, et al. **Endocrinology** 1981 Aug; 109(2):544–7

Clinical tolerability of ibopamine hydrochloride (SB 7505). Melloni GF, et al. **Eur J Clin Pharmacol** 1981;19(6):409–11

Pharmacological studies with several analogs of mazindol: correlation between effects on dopamine uptake and various in vivo responses. Heikkila RE, et al. **Eur J Pharmacol** 1981 May 8;71(2–3):277–86

Behavioral effects of unilateral dopamine injection into dorsal or ventral striatum. Joyce JN, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):1–10

Differential effects of dopamine agonists in mature and immature rats. McDevitt JT, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):69–75

Endogenous alpha-melanotropin and central dopamine systems in physical and psychological stress. Monnet F, et al. **Exp Brain Res** 1981; 42(2):203–11

Effect of dopamine agonists and antagonists on the electrical activity of substantia nigra neurons transplanted into the lateral ventricle of the rat. Wuerthele SM, et al. **Exp Brain Res** 1981;44(1):1–10

3-Hydroxy-4-methoxyphenethylamine, the cardioactive constituent of a soft coral. Gregson RP, et al. **Experientia** 1981 May 15;37(5):493–4

The acute effects of sulpiride on the central dopamine turnover in rats: a quantitative histochemical study. Yoshida M, et al. **Experientia** 1981 May 15;37(5):491–2

Effects of exposure to trichloroethylene and tetrachloroethylene on the contents of acetylcholine, dopamine, norepinephrine and serotonin in rat brain. Honma T, et al. **Ind Health** 1980;18(4):171–8

Effects of dopamine on chemoreflexes in breathing. Nishino T, et al. **J Appl Physiol** 1981 Apr;50(4):892–7

Stereospecific antagonism by d-butaclamol of dopamine-induced relaxation of the isolated rabbit mesenteric artery. Brodde OE, et al. **J Cardiovasc Pharmacol** 1981 Jul–Aug;3(4):828–37

Studies on dopamine-converting enzymes in human plasma. Allenmark S, et al. **J Chromatogr** 1981 Apr 10;223(1):188–92

Effects of L-dopa on dopamine and norepinephrine concentrations in rat brain assessed by gas chromatography. Doshi PS, et al. **J Chromatogr** 1981 Jun 19;210(3):505–11

Effect of gonadectomy on the concentrations of catecholamines in discrete areas of the diencephalon of the domestic fowl. Knight PG, et al. **J Endocrinol** 1981 Jun;89(3):389–97

Synthesis and pharmacological evaluation of sulfonium analogues of dopamine: nonclassical dopamine agonists. Anderson K, et al. **J Med Chem** 1981 Jun;24(6):683–7

Synthesis and evaluation of novel alkylpiperazines as potential dopamine antagonists. Glennon RA, et al. **J Med Chem** 1981 Jun;24(6):678–83

Cyclic adenosine monophosphate modulation of contractility via slow Ca2+ channels in chick heart. Azuma J, et al. **J Mol Cell Cardiol** 1981 Jun;13(6):577–87

Characterisation of inhibitory 5-hydroxytryptamine receptors that modulate dopamine release in the striatum. Ennis C, et al. **J Neurochem** 1981 Apr;36(4):1515–20

Effect of guanine nucleotides on dopaminergic agonist and antagonist affinity for [3H]sulpiride binding sites in rat striatal membrane preparations. Freedman SB, et al. **J Neurochem** 1981 Sep; 37(3):608–12

Involvement of brain monoamines in the delta-9-tetrahydrocannabinol-induced reduction of hippocampal choline uptake. Lindamood C 3d, et al. **J Neurochem** 1981 Sep; 37(3):788–91

Diurnal variations in monoamine contents in discrete brain regions of the mongolian gerbil (Meriones unguiculatus). Matsumoto M, et al. **J Neurochem** 1981 Sep;37(3):792–4

Benzodiazepine antagonist Ro 15–1788: binding characteristics and interaction with drug-induced changes in dopamine turnover and cerebellar cGMP levels. Möhler H, et al. **J Neurochem** 1981 Sep; 37(3):714–22

A rapid and simple method for the determination of picogram levels of 3-methoxytyramine in brain tissue using liquid chromatography with electrochemical detection. Ponzio F, et al. **J Neurochem** 1981 Apr; 36(4):1361–7

Alteration of dopamine synthesis in rat striatum subsequent to selective type A monoamine oxidase inhibition. Schoepp DD, et al. **J Neurochem** 1981 Aug;37(2):527–30

Neuronal responses of the globus pallidus to systemic administration of d-amphetamine: investigation of the involvement of dopamine, norepinephrine, and serotonin. Bergstrom DA, et al. **J Neurosci** 1981 Mar;1(3):292–9

High-performance liquid chromatography with electrochemical detection as a highly efficient tool for studying catecholaminergic systems. I. Quantification of noradrenaline, adrenaline and dopamine in cultured adrenal medullary cells. Müller TH, et al. **J Neurosci Methods** 1981 Jun;4(1):39–52

Relevance of the rodent area postrema to dopamine-dependent behavioural effects. Costall B, et al. **J Pharm Pharmacol** 1981 Apr; 33(4):257–9

Lowering of dopamine metabolites in rat brain by harmaline. Fuller RW, et al. **J Pharm Pharmacol** 1981 Apr;33(4):255–6

Effect of GABAergic drugs on dopamine catabolism in the nigrostriatal and mesolimbic dopaminergic pathways of the rat. Gundlach AL, et al. **J Pharm Pharmacol** 1981 Jan;33(1):41–3

Comparative effects of classical and atypical antipsychotic drugs in combination with a non-amphetamine stimulant on rat brain dopamine metabolism. McMillen BA. **J Pharm Pharmacol** 1981 Aug; 33(8):544–6

Influence of deaminated metabolites on the relaxing effect of dopamine on dog saphenous vein. Teixeira F, et al. **J Pharm Pharmacol** 1981 Aug; 33(8):529–33

Dopamine and its antagonists on molluscan smooth muscle. Yoshida Y, et al. **J Pharmacobiodyn** 1981 Mar;4(3):226–8

Haloperidol-induced reduction of nigral substance P-like immunoreactivity: a probe for the interactions between dopamine and substance P neuronal systems. Hanson GR, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):568–74

Alteration of aminophylline-induced respiratory stimulation by perturbation of biogenic amine systems. Mueller RA, et al. **J Pharmacol Exp Ther** 1981 Sep;218(3):593–9

Effects of CDP-choline on striatal dopamine level and behavior in rats. Shibuya M, et al. **Jpn J Pharmacol** 1981 Feb;31(1):47–52

Increase in rat striatal acetylcholine content by bromocriptine: evidence for an indirect dopaminergic action. Consolo S, et al. **Life Sci** 1981 Aug 3;29(5):457–65

Striatal muscarinic receptors: regulation by dopaminergic agonists. Ehlert FJ, et al. **Life Sci** 1981 May 21;28(21):2441–8

Acute choline administration in rat and mouse: no effect on dopamine metabolism in brain. Flentge F, et al. **Life Sci** 1981 Jul 27; 29(4):331–5

Differential effects of several dopamine uptake inhibitors and releasing agents on locomotor activity in normal and in reserpinized mice. Heikkila RE. **Life Sci** 1981 Apr 27;28(17):1867–73

Studies on axonal transport in dopaminergic neurons: effect of neuropharmacologic lesions. Iwamoto ET. **Life Sci** 1981 May 11; 28(19):2179–86

Dopamine independent rotational response to unilateral intranigral injection of serotonin. Oberlander C, et al. **Life Sci** 1981 Jun 8; 28(23):2595–601

Biochemical effects of quipazine on rat striatal dopaminergic system. Ponzio F, et al. **Life Sci** 1981 Jul 6;29(1):83–91

Dopaminergic agonist and antagonist effects on striatal tyrosine hydroxylase distribution. Smith CP, et al. **Life Sci** 1981 Jan 12; 28(2):193–7

Tyrosine availability and dopamine synthesis in the striatum: studies with gamma-butyrolactone. Svod A, et al. **Life Sci** 1981 Aug 17; 29(7):743–8

Stimulation of dopamine synthesis and release by morphine and D-ala2-D-leu5-enkephalin in the mouse striatum in vivo. Urwyler S, et al. **Life Sci** 1981 May 18;28(20):2277–86

Manic depression—a disorder of central dopaminergic rhythm. Skutsch GM. **Med Hypotheses** 1981 Jun;7(6):737–46

Dopamine receptor mediated inhibition by pergolide of electrically-evoked 3H-dopamine release from striatal slices of cat and rat: slight effect of ascorbate. Lehmann J, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Aug;317(1):31–5

Pathways of dopamine metabolism in the rabbit caudate nucleus in vitro. Zumstein A, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jun; 316(3):205–17

Age-related changes in dopamine, LHRH and somatostatin in the rat hypothalamus. Hoffman GE, et al. **Neurobiol Aging** 1980 Summer; 1(1):27–37

The effect of hypoxia on monoamine levels in discrete regions of aged rat brain. Roubein IF, et al. **Neurobiol Aging** 1981 Spring;2(1):37–40

Release of radiolabeled dopamine, p-tyramine, and m-tyramine from rat striatal slices by some aminotetralins. Dyck LE. **Neurochem Res** 1981 Apr;6(4):365–75

Hyperprolactinemia counteracts the testosterone-induced inhibition of the preoptic area dopamine turnover. Kalra PS, et al. **Neuroendocrinology** 1981 Aug;33(2):118–22

Characteristics of dopamine release from isolated nerve endings of the tuberoinfundibular neurones. Annunziato L, et al. **Neuropharmacology** 1981 Aug;20(8):727–31

The role of 5-hydroxytryptamine in dopamine-dependent stereotyped behaviour. Carter CJ, et al. **Neuropharmacology** 1981 Mar; 20(3):261–5

Altered paw preference after unilateral 6-hydroxy-dopamine injections into lateral hypothalamus. Uguru-Okorie DC, et al. **Neuropsychologia** 1981;19(3):463–7

Brain levels of noradrenalin, dopamine, and serotonin in rats with different levels of motor activity. Semenova TP, et al. **Neurosci Behav Physiol** 1981 Mar–Apr;11(2):153–5

Dopamine-induced ventilatory depression in the rat, mediated by carotid nerve afferents. Cardenas H, et al. **Neurosci Lett** 1981 Jun 12;

24(1):29-33

Histochemical evidence for a catecholaminergic (presumably dopaminergic) projection from the ventral mesencephalic tegmentum to visual cortex in the cat. Törk I, et al. **Neurosci Lett** 1981 Jul 17; 24(3):215-9

Membrane activation of smooth muscle from rabbit basilar artery by dopamine. Harder DR. **Pflugers Arch** 1981 Jun;390(3):296-8

Effects on central dopaminergic systems of d-coclaurine and d-reticuline, extracted from Magnolia salicifolia. Watanabe H, et al. **Planta Med** 1981 Jul;42(3):213-22

Effect of combined treatment with dopaminergic and GABA-ergic drugs on the threshold for maximal electroconvulsions in mice. Czuczwar SJ. **Pol J Pharmacol Pharm** 1981 Jan-Feb;33(1):25-35

Dopaminergic regulation of muscarinic receptor binding in the corpus striatum. Ehlert FJ, et al. **Proc West Pharmacol Soc** 1981;24:93-5

Noradrenergic and dopaminergic interactions in escape behavior: analysis of uncontrollable stress effects. Anisman H, et al. **Psychopharmacology (Berlin)** 1981;74(3):263-8

Differential effects of IV and IP muscimol on central dopamine metabolism. Gundlach AL, et al. **Psychopharmacology (Berlin)** 1981; 74(1):71-3

Cathinone, an alkaloid from khat leaves with an amphetamine-like releasing effect. Kalix P. **Psychopharmacology (Berlin)** 1981; 74(3):269-70

Cageing density and dopamine striatal elimination after amphetamine in the rat. Lokiec F, et al. **Psychopharmacology (Berlin)** 1981; 73(4):402-3

Role of dopamine in the diuresis caused by stimulation of atrial receptors. Linden RJ, et al. **Q J Exp Physiol** 1981 Apr;66(2):155-61

Effect of imipramine on high potassium evoked 3H-dopamine release in the rat striatum. Kamiya H, et al. **Res Commun Chem Pathol Pharmacol** 1981 Jul;33(1):49-60

Concomitant analysis of normetanephrine and 3-methoxytyramine in brain: a new gas-liquid chromatography procedure. LeGatt DF, et al. **Res Commun Chem Pathol Pharmacol** 1981 Jul;33(1):61-8

The posterior pituitary: regulation of anterior pituitary prolactin secretion. Peters LL, et al. **Science** 1981 Aug 7;213(4508):659-61

Effect of dopamine on renal haemodynamics in the denervated dog kidney. Huland H, et al. **Urol Res** 1981 Mar 17;9(1):5-11

[Effect of the organophosphorus compound neguvon on the dopamine content in the rat brain] Dishovski K, et al. **Eksp Med Morfol** 1981; 20(2):62-6 (Eng. Abstr.) (Bul)

[Effect of piracetam and dihydroergotoxine on the release of dopamine from the corpus striatum of the rat] Wustmann C, et al. **Acta Biol Med Ger** 1980;39(8-9):383-5 (Ger)

[Effect of dopamine and its antagonists on contractile activity of the lower esophageal sphincter and the stomach (author's transl)] Itoh Z, et al. **Nippon Heikatsukin Gakkai Zasshi** 1980 Jun;16(2):99-107 (Eng. Abstr.) (Jpn)

[Increase in the affinity of hypothalamic tyrosine hydroxylase for tyrosine as a result of the action of dopamine on the synaptosome membrane] Mineeva MF, et al. **Dokl Akad Nauk SSSR** 1981;258(2):501-4 (Rus)

[Effect of certain GABA-ergic substances on dopamine metabolism in the rat brain] Malikova LA, et al. **Farmakol Toksikol** 1981 Jan-Feb; 44(1):37-40 (Eng. Abstr.) (Rus)

[Dopamine concentration in the nigro-striatal system during elaboration and performance of conditioned avoidance reactions of various complexity in rats] Saul'skaia NB. **Fiziol Zh SSSR** 1981 Jun; 67(6):797-803 (Eng. Abstr.) (Rus)

[Participation of the thymus in effecting the modulating influence of the dopaminergic system on immunogenesis] Al'perina EL. **Vestn Akad Med Nauk SSSR** 1981;(5):30-3 (Eng. Abstr.) (Rus)

DOPAMINE BETA-HYDROXYLASE

Immunofluorescence of dopamine-beta-hydroxylase in small intensely fluorescent cells of human sympathetic ganglia. Schröder H, et al. **Acta Anat (Basel)** 1981 Jan;109(1):47-50

The effect of intracerebroventricularly administered dibutyryl adenosine 3',5'-cyclic monophosphate on cerebrospinal fluid and serum dopamine-beta-hydroxylase in rabbits. Fraeyman NH, et al. **Biochem Pharmacol** 1981 Jul 1;30(13):1765-9

Studies on the interaction of Cibacron Blue and Procion Red with dopamine beta-monooxygenase. Skotland T. **Biochim Biophys Acta** 1981 Jun 15;659(2):312-25

Comparison of midday serum dopamine-beta-hydroxylase activity in depressed patients and normal controls. Nasr S, et al. **Commun Psychopharmacol** 1980;4(4):263-7

Estradiol concentration in dopamine-beta-hydroxylase containing neurons of lower brain stem demonstrated by combined autoradiography and immunohistochemistry. Sar M, et al. **Exp Brain Res** 1981; Suppl 3:29-36

Palmar skin potential reflex and serum dopamine-beta-hydroxylase activity of the aged. Nomura S, et al. **Folia Psychiatr Neurol Jpn** 1981; 35(1):3-9

Heterogeneity in the adrenomedullary storage of catecholamines, ATP, calcium and releasable dopamine beta-hydroxylase activity. Bolstad G, et al. **J Auton Nerv Syst** 1980 Dec;2(4):337-54

Dopamine beta-hydroxylase. Comparative specificities and mechanisms of the oxygenation reactions. May SW, et al. **J Biol Chem** 1981 Aug 25;256(16):8470-5

Studies on dopamine-converting enzymes in human plasma. Allenmark S, et al. **J Chromatogr** 1981 Apr 10;223(1):188-42

Ultrastructural demonstration of noradrenergic synapses in the rat central nervous system by dopamine-beta-hydroxylase immunocytochemistry. Olschowka JA, et al. **J Histochem Cytochem** 1981 Feb;29(2):271-80

Influence of sino-aortic baroreceptor denervation on catecholamines, catecholamine-synthesizing enzymes and choline acetyltransferase activity in the brainstem nuclei of the rat. Nakamura K, et al. **Jpn J Pharmacol** 1981 Feb;31(1):95-105

Compensatory increase in adrenal weight and dopamine-beta-hydroxylase activity after unilateral adrenalectomy: experimental evidence for a pineal-dependent contribution. Banerji TK, et al. **Proc Soc Exp Biol Med** 1981 Sep;167(4):514-8

DOSE-RESPONSE RELATIONSHIP, DRUG

Dose dependence of the thyrotropin (TSH) receptor damaging effect of gonadotropin in the newborn rats. Nagy SU, et al. **Acta Physiol Acad Sci Hung** 1980;56(4):417-20

DOXEPIN

Doxepin plasma levels and anxiolytic response. Norman TR, et al. **Int Pharmacopsychiatry** 1980;15(4):247-52

Malignant breast change in man given two drugs associated with breast hyperplasia [letter] Smedley HM. **Lancet** 1981 Sep 19; 2 Pt 1(8247):638-9

DRUG EVALUATION

Guidelines for the evaluation of drugs in the elderly neuropsychiatric patient (demented and non-demented). **Pharmacopsychiatria** 1981 Jul; 14(4):150-4 contd

[Effectiveness of drug testing with the help of psychometric methods. Possibilities and problems] Oswald WD. **Med Welt** 1981 Aug 21; 32(34):1225-31 (Ger)

ELECTROCONVULSIVE THERAPY

Effect of electroconvulsive treatment on brain monoamine content, pituitary-adrenal function and plasma prolactin. Arató M, et al. **Acta Physiol Acad Sci Hung** 1980;56(2):163-71

Animal model of depression: effects of electroconvulsive shock therapy. Katz RJ. **Neurosci Biobehav Rev** 1981 Summer;5(2):273-7

Influence of unilateral ECT on tryptophan metabolism in endogenous depression. Smith DF, et al. **Pharmacopsychiatria** 1981 Jul; 14(4):135-8

Electroconvulsive therapy in the medically ill patient. Bidder TG. **Psychiatr Clin North Am** 1981 Aug;4(2):391-405 (60 ref.)

Substance P-like immunoreactivity in plasma of psychotic patients and effects of neuroleptics and electroconvulsive therapy. Kaiya H, et al. **Psychiatry Res** 1981 Aug;5(1):11-21

Studies on possible mechanisms of action of electroconvulsive therapy; effects of repeated electrically induced seizures on rat brain receptors for monoamines and other neurotransmitters. Deakin JF, et al. **Psychopharmacology (Berlin)** 1981;73(4):345-9

[Tricyclics, MAOI and electroshock therapy in the treatment of depressive syndromes] Carolei A, et al. **Clin Ter** 1981 Jul 15;98(1):75-86 (29 ref.) (Ita)

ELECTROENCEPHALOGRAPHY

Effect of estazolam on the caudate spindle in the cat. Janicki P, et al. **Act Nerv Super (Praha)** 1981 Jun;23(2):172-3

Pharmacoelectroencephalographic study of brotizolam, a novel hypnotic. Fink M, et al. **Clin Pharmacol Ther** 1981 Sep;30(3):336-42

Drug-specific EEG frequency spectra and their time courses produced in the cat by antidepressants and a benzodiazepine. Fairchild MD, et al. **Electroencephalogr Clin Neurophysiol** 1981 Jul;52(1):81-8

Effect of a short-acting benzodiazepine on brain electrical activity during sleep. Johnson LC, et al. **Electroencephalogr Clin Neurophysiol** 1981 Jul;52(1):89-97

Effects of gonadal steroids on EEG and performance in the human. Becker D, et al. **Exp Brain Res** 1981;Suppl 3:309-17

Bilateral skin conductance, finger pulse volume, and EEG orienting response to tones of differing intensities in chronic schizophrenics and controls. Bernstein AS, et al. **J Nerv Ment Dis** 1981 Aug; 169(8):513-28

The effect of imipramine and mianserin on the behavior and EEG afterdischarges induced by single electric stimulation of the rabbit amygdala. Ossowska K, et al. **Pol J Pharmacol Pharm** 1980 Jul-Aug; 32(4):513-22

The effects of haloperidol on the EEG spectrum. Wieneke GH, et al. **Psychopharmacology (Berlin)** 1981;74(1):33-4

[Analysis of auditory averaged evoked potentials (AEP)– description of a fully automated procedure for AEP analysis (author's transl)] Hofmann W, et al. **EEG EMG** 1981 Jun;12(2):84–9 (Eng. Abstr.) (Ger)

[Effects of diazepam and thiamylal on reticular multi–unit activity, visual evoked responses, EEG and arterial blood pressure in rabbits (author's transl)] Ueda Y. **Nippon Geka Hokan** 1980 Sep 1;49(5):595–607 (Eng. Abstr.) (Jpn)

[Cerebral bioelectric activity and urinary catecholamine elimination in thermal stress in children] Stratone A, et al. **Rev Med Chir Soc Med Nat Iasi** 1981;85(1):113–6 (Eng. Abstr.) (Rum)

ELECTROLYTES

Endogenous norepinephrine release induced by tyramine modulates intestinal ion transport. Tapper EJ, et al. **Am J Physiol** 1981 Sep; 241(3):G264–9

Measurement of active ion transport in man. Utilizing intact human erythrocytes. Micheis RC, et al. **Ann Clin Lab Sci** 1981 Mar–Apr; 11(2):158–64

The effect of lithium on electrolyte transport by the in situ choroid plexus of the cat. Reed DJ, et al. **J Physiol (Lond)** 1980 Dec;309:329–39

[Effect of acetylcholine and histamine on electrolyte and catecholamine content of vessel walls exposed to x–rays and cystamine] Litvinov SA. **Farmakol Toksikol** 1981 Jan–Feb;44(1):55–9 (Eng. Abstr.) (Rus)

ELECTROSHOCK

Effect of electroconvulsive shock on beta–endorphin immunoreactivity of rat brain, pituitary gland, and plasma. Dias RD, et al. **Behav Neural Biol** 1981 Jun;32(2):265–8

Differential effects of electroconvulsive shock and antidepressant drugs on serotonin–2 receptors in rat brain. Kellar KJ, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):515–8

Effect of combined treatment with dopaminergic and GABA–ergic drugs on the threshold for maximal electroconvulsions in mice. Czuczwar SJ. **Pol J Pharmacol Pharm** 1981 Jan–Feb;33(1):25–35

EMOTIONS

Psychophysiological responses of schizophrenic patients to high and low expressed emotion relatives. Sturgeon D, et al. **Br J Psychiatry** 1981 Jan;138:40–5

The effect of five tricyclic antidepressants on salivary flow and mood in healthy volunteers. Blackwell B, et al. **Commun Psychopharmacol** 1980;4(4):255–61

Antianxiety agents and emotional behavior, an information processing analysis. Morris MD, et al. **Prog Neuropsychopharmacol** 1981; 5(3):219–40

ENDORPHINS

The investigation of [(4'–amino)–PHE]4–enkephalin conformation in water by the spectrofluorimetric procedure. Jankowski A, et al. **Acta Biochim Pol** 1981;28(1):11–20

Interaction of tritiated beta–endorphin with rat brain membranes. Hammonds RG Jr, et al. **Anal Biochem** 1981 Jun;114(1):75–84

Effect of electroconvulsive shock on beta–endorphin immunoreactivity of rat brain, pituitary gland, and plasma. Dias RD, et al. **Behav Neural Biol** 1981 Jun;32(2):265–8

Evidence for an opiate–inactive N–acetylated derivative of leucine–enkephalin in the rat neurointermediate pituitary. Seizinger BR, et al. **Biochem Biophys Res Commun** 1981 Jul 16;101(1):289–97

Synthetic N–dimethyl beta–endorphin, a stabilized opioid peptide. Boarder MR, et al. **Biochem Pharmacol** 1981 Jun 1;30(11):1289–93

A reaction of acetaldehyde with enkephalins and related peptides. Summers MC, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1621–7

Acetaldehyde––enkephalins: structure proof and some conformational deductions from one– and two–dimensional proton nuclear magnetic resonance spectra. Gidley MJ, et al. **Biochemistry** 1981 Jun 23; 20(13):3880–3

Conformational properties of central nervous system myelin basic protein, beta–endorphin, and beta–lipotropin in water and in the presence of anionic lipids. Mattice WL, et al. **Biopolymers** 1981 Jul; 20(7):1421–34

The effects of morphine and methionine–enkephalin on the release of purines from cerebral cortex slices of rats and mice. Stone TW. **Br J Pharmacol** 1981 Sep;74(1):171–6

Enkephalins, substance P, bradykinin and angiotensin II: differential sites of action on the hypothalamo–neurohypophysial system. Baertschi AJ, et al. **Brain Res** 1981 Sep 7;220(1):107–19

Strain differences in pituitary beta–endorphin and ACTH content in inbred mice. Crabbe JC Jr, et al. **Brain Res** 1981 Aug 24; 219(1):219–23

Development of acute tolerance during exposure of hippocampal explants to an opioid peptide. Gähwiler BH. **Brain Res** 1981 Jul 27; 217(1):196–200

Differential response to methionine–enkephalin in basal hypothalamus and preoptic area following hypothalamic deafferentation. Kalra SP, et al. **Brain Res** 1981 Jun 29;215(1–2):410–3

Met–enkephalin concentrations in individual brain nuclei of ansa lenticularis and stria terminalis transected rats. Palkovits M, et al. **Brain Res** 1981 Jul 6;216(1):203–9

Opiate effects on rabbit vagus nerve: electrophysiology and radioligand binding. Shefner SA, et al. **Brain Res** 1981 Sep 21;221(1):109–16

Mechanism of kyotorphin–induced release of Met–enkephalin from guinea pig striatum and spinal cord. Shiomi H, et al. **Brain Res** 1981 Sep 21; 221(1):161–9

Comparative immunocytochemical localization of enkephalin and somatostatin in the median eminence, hypothalamus and adjacent areas of the guinea–pig brain. Tramu G, et al. **Brain Res** 1981 Jun 29; 215(1–2):235–55

Thermoregulatory effects of centrally administered bombesin, bradykinin, and methionine–enkephalin. Francesconi R, et al. **Brain Res Bull** 1981 Jul;7(1):63–8

Immunohistochemical localisation of substances reactive to antisera against alpha– and beta–endorphin and met–enkephalin in the brain of Rana temporaria L. Doerr–Schott J, et al. **Cell Tissue Res** 1981; 217(1):79–92

Immunohistochemical evidence of methionine enkephalin–like material in the brain of the migratory locust. Rémy C, et al. **Cell Tissue Res** 1981;218(2):271–8

Processing, turnover and release of corticotropins, endorphins and melanotropin in the toad pituitary intermediate lobe. Loh YP. **Ciba Found Symp** 1981;(81):55–78

Comparison of rat anterior and intermediate pituitary in tissue culture: corticotropin (ACTH) and beta–endorphin. Mains RE, et al. **Ciba Found Symp** 1981;(81):32–54

beta–lipotrophin and beta–endorphin plasma levels during pregnancy. Genazzani AR, et al. **Clin Endocrinol (Oxf)** 1981 Apr;14(4):409–18

Alpha–adrenergic stimulation by clonidine increases plasma concentrations of immunoreactive beta–endorphin in rats. Pettibone DJ, et al. **Endocrinology** 1981 Sep;109(3):798–802

Evidence that a serotonergic mechanism stimulates the secretion of pituitary beta–endorphin–like immunoreactivity in the rat. Sapun DI, et al. **Endocrinology** 1981 Aug;109(2):421–6

Epinephrine as a potent releaser of immunoreactive beta–endorphin in rats. Berkenbosch F, et al. **Eur J Pharmacol** 1981 Jun 10; 72(1):97–100

Effect of chronic morphine treatment on beta–endorphin biosynthesis by the rat neurointermediate lobe. Gianoulakis C, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):313–21

Comparison of the effects of beta–endorphin and morphine on exploratory and socio–sexual behaviour in the male rat. Meyerson BJ. **Eur J Pharmacol** 1981 Feb 19;69(4):453–63

Potentiation by Des–Tyr–gamma–endorphin on apomorphine–induced changes in rat open field behavior. Nickolson VJ. **Eur J Pharmacol** 1981 Jun 10;72(1):77–81

Bombesin, calcitonin and leu–enkephalin immunoreactivity in endocrine cells of human lung. Cutz E, et al. **Experientia** 1981 Jul 15; 37(7):765–7

(D–Ala2, N–Val5), (D–Ala2, Met5) enkephalins and enkephalinamides. Correlation between biological activity and NMR features. Gairin JE, et al. **FEBS Lett** 1981 Jun 1;128(1):51–4

N–(9–Xanthenyl)amino acid N–carboxyanhydrides in the solid–phase synthesis of a Lys–Lys–linked cyclic leucine–enkephalin. Halstrøm J, et al. **Hoppe Seylers Z Physiol Chem** 1981 Jun;362(6):593–9

Effect of glucose and arginine on L–enkephalin secretion of the isolated perfused rat pancreas. Sachse G, et al. **Horm Metab Res** 1981 Jun; 13(6):360

Subcellular fractionation studies on the post–translational processing of pro–adrenocorticotropic hormone/endorphin in rat intermediate pituitary. Glembotski CC. **J Biol Chem** 1981 Jul 25;256(14):7433–9

Distribution of methionine–enkephalin immunoreactivity in the chick brain: an immunohistochemical study. de Lanerolle NC, et al. **J Comp Neurol** 1981 Jul 10;199(4):513–33

The immunocytochemical localization of enkephalin in the central nervous system of the rat. Finley JC, et al. **J Comp Neurol** 1981 Jun 1; 198(4):541–65

Immunohistochemical localization of enkephalin in the central nervous system and pituitary of the lizard, Anolis carolinensis. Naik DR, et al. **J Comp Neurol** 1981 Jun 1;198(4):583–601

Neuropeptides in striato–nigral pathways. Cuello AC, et al. **J Neural Transm** 1981;51(1–2):83–96

Long–term treatment of rats with morphine reduces the activity of messenger ribonucleic acid coding for the beta–endorphin/ACTH precursor in the intermediate pituitary. Höllt V, et al. **J Neurochem** 1981 Sep;37(3):619–26

Methionine–enkephalin and morphine: amount ejected microiontophoretically. Hosford DA, et al. **J Neurosci Methods** 1981 Aug;4(2):135–9

The effect of barbiturates on the degradation of enkephalin by brain enzymes. Altstein M, et al. **Life Sci** 1981 Jun 12;28(2):185-91

Neurochemical studies in the hypoxic brain: substance P, met-enkephalin, GABA and angiotensin converting enzyme. Arregui A, et al. **Life Sci** 1981 Jun 29;28(26):2925-9

A distinct peptidyl dipeptidase that degrades enkephalin: exceptionally high activity in rabbit kidney. Benuck M, et al. **Life Sci** 1981 Jun 8; 28(23):2643-50

Opioid activities of beta-casomorphins. Brantl V, et al. **Life Sci** 1981 Apr 27;28(17):1903-9

Intracerebral des-tyrosine-gamma-endorphin inhibits methylphenidate induced locomotor activity. Davis KL, et al. **Life Sci** 1981 May 21; 28(21):2421-4

Rapid depletion and restoration of striatal met-enkephalin after ketamine. Fratta W, et al. **Life Sci** 1981 Jul 6;29(1):93-7

Peptide hormone degradation by a rat mast cell chymase-heparin complex. Jahnke GD, et al. **Life Sci** 1981 Jul 27;29(4):397-403

Sensitive and specific high performance liquid chromatographic method for methionine and leucine enkephalins. Mousa S, et al. **Life Sci** 1981 Jul 6;29(1):61-8

Stimulation of dopamine synthesis and release by morphine and D-ala2-D-leu5-enkephalin in the mouse striatum in vivo. Urwyler S, et al. **Life Sci** 1981 May 18;28(20):2277-86

Behavioral and neurochemical effects of the new opioid peptide dynorphin--(1-13): comparison with other neuropeptides. Zwiers H, et al. **Life Sci** 1981 Jun 1;28(22):2545-51

Parallel stimulation of ACTH, beta-LPH + beta-endorphin and alpha-MSH release by alpha-adrenergic agents in rat anterior pituitary cells in culture. Raymond V, et al. **Mol Cell Endocrinol** 1981 Jun; 22(3):295-303

Endorphins and ventilatory control [letter] **N Engl J Med** 1981 Oct 15; 305(16):958-60

What makes us run? [editorial] Appenzeller O. **N Engl J Med** 1981 Sep 3;305(10):578-80

Catecholamines, dopamine, and endorphin levels during extreme exercise [letter] Bortz WM 2d, et al. **N Engl J Med** 1981 Aug 20; 305(8):466-7

Physical conditioning facilitates the exercise-induced secretion of beta-endorphin and beta-lipotropin in women. Carr DB, et al. **N Engl J Med** 1981 Sep 3;305(10):560-3

An opiate system in the goldfish retina. Djamgoz MB, et al. **Nature** 1981 Aug 13;292(5824):620-3

Super-active enkephalin analogues. Simple tripeptide hydroxyalkylamides exhibit surprisingly high and long-lasting opioid activities. Kiso Y, et al. **Naturwissenschaften** 1981 Apr;68(4):210-2

Vasopressin stimulates release of beta-lipotropin and beta-endorphin in conscious rats as measured by radioimmunoassay of unextracted plasma. Anhut H, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb; 316(1):59-63

Clozapine inhibition of metenkephalin binding to synaptosome-enriched fractions of rat whole brain and hippocampus. Somoza E, et al. **Neurochem Res** 1981 Apr;6(4):413-24

Immunocytochemical localization of beta-endorphin-containing neurons in the rat brain. Finley JC, et al. **Neuroendocrinology** 1981 Jul; 33(1):28-42

In vivo characterization of the mechanisms that secrete enkephalin-like peptides stored in dog adrenal medulla. Govoni S, et al. **Neuropharmacology** 1981 Jul;20(7):639-45

Multi-dimensional analyses of behavior in mice treated with alpha-endorphin. Kameyama T, et al. **Neuropharmacology** 1981 Mar; 20(3):247-50

Isolation and identification of an analgesic opioid dipeptide kyotorphin (Tyr-Arg) from bovine brain. Shiomi H, et al. **Neuropharmacology** 1981 Jul;20(7):633-8

In vivo release of enkephalin from the globus pallidus. Bayon A, et al. **Neurosci Lett** 1981 Jun 12;24(1):65-70

Diffuse enkephalin innervation from caudate to globus pallidus. Correa FM, et al. **Neurosci Lett** 1981 Aug 7;25(1):63-8

Reciprocal antagonism between ACTH1-24 and beta-endorphin in rats. Fratta W, et al. **Neurosci Lett** 1981 Jun 12;24(1):71-4

Release of immunoreactive-dynorphin from the isolated guinea-pig small intestine is reduced during peristaltic activity. Kromer W, et al. **Neurosci Lett** 1981 Aug 7;25(1):53-6

The influence of foot-shock stress upon brain, pituitary and spinal cord pools of immunoreactive dynorphin in rats. Millan MJ, et al. **Neurosci Lett** 1981 Jun 12;24(1):75-9

Effects of bromocriptine on receptor binding of methionine-enkephalin. Ogawa N, et al. **Neurosci Lett** 1981 May 6;23(2):215-8

Correlation between Met-enkephalin and substance P immunoreactivity in the primate globus pallidus. Haber S, et al. **Neuroscience** 1981; 6(7):1291-7

Co-localization of neurophysin- and enkephalin-like immunoreactivity in cat pituitary. Coulter HD, et al. **Peptides (Fayetteville)** 1981; 2 Suppl 1:51-5

Regional distribution of gamma- and beta-endorphin-like peptides in the pituitary and brain of the rat. Dorsa DM, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:71-7

Effects of alpha-MSH and beta-endorphin on startle reflex in rat. Hoehler FK, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:137-41

Substance P and leucine-enkephalin changes after chordotomy and morphine treatment. Naftchi NE, et al. **Peptides (Fayetteville)** 1981; 2 Suppl 1:61-70

Presence of leucine-enkephalin in organotypic explants of fetal mouse spinal cord. Naftchi NE, et al. **Peptides (Fayetteville)** 1981; 2 Suppl 1:57-60

Muscarinic cholinergic influences on ACTH and beta-endorphin release mechanisms in human subjects. Risch SC, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:95-7

Localization and opiate receptor binding of enkephalin, CCK and ACTH/beta-endorphin in the rat central nervous system. Stengaard-Pedersen K, et al. **Peptides (Fayetteville)** 1981; 2 Suppl 1:3-19 (53 ref.)

Peptides as neurotransmitters: focus on the enkephalins and endorphins. Miller RJ. **Pharmacol Ther [B]** 1981;12(1):73-108 (214 ref.)

Endogenous opioids and cyclic AMP. Wollemann M. **Prog Neurobiol** 1981;16(2):145-54 (76 ref.)

Effect of carbamazepine on CSF opioid activity; relationship to antidepressant response. Post RM, et al. **Psychiatry Res** 1981 Aug; 5(1):59-66

(Des-Tyr)-gamma-endorphin in the treatment of schizophrenia. Manchanda R, et al. **Psychol Med** 1981 May;11(2):401-4

Effects of opioid peptides on synaptic potentials in explants of rat hippocampus. Gähwiler BH, et al. **Regul Pept** 1981 Feb;1(5):317-26

Presence of dynorphin-like immunoreactivity in rat pituitary gland and hypothalamus. Nakao K, et al. **Regul Pept** 1981 Jun;2(3):201-8

Immunohistochemical localization of gastrin C-terminus, gastric inhibitory peptide (GIP) and endorphin in the pancreas of lizards with special reference to the hibernation period. El-Salhy M, et al. **Regul Pept** 1981 May;2(2):97-111

Anatomical distribution and physiological effects of enkephalin in rat inferior olive. Schulman JA. **Regul Pept** 1981 May;2(2):125-37

Endogenous opiates and fasting [letter] Ettenberg A, et al. **Science** 1981 Sep 11;213(4513):1282

Characterization of a 41-residue ovine hypothalamic peptide that stimulates secretion of corticotropin and beta-endorphin. Vale W, et al. **Science** 1981 Sep 18;213(4514):1394-7

[Endogenous opiate-like substances and cardiovascular activity (author's transl)] Zhang F, et al. **Sheng Li Ko Hsueh Chin Chan** 1980 Apr; 11(4):365-7 **(Chi)**

ENURESIS

Voiding dysfunction in the child with problem 'wetting'. Noe HN. **JDBP** 1980 Mar;1(1):29-33

EPHEDRINE

Experimental motion sickness: efficacy of transdermal scopolamine plus ephedrine. Graybiel A, et al. **Aviat Space Environ Med** 1981 Jun; 52(6):337-9

Dopamine-like properties of ephedrine in rat brain. Zarrindast MR. **Br J Pharmacol** 1981 Sep;74(1):119-22

Sensitive assay for pseudoephedrine and its metabolite, norpseudoephedrine in plasma and urine using gas-liquid chromatography with electron-capture detection. Lo LY, et al. **J Chromatogr** 1981 Feb 13;222(2):297-302

Stereospecific radioimmunoassays for d-pseudoephedrine in human plasma and their application to bioequivalency studies. Findlay JW, et al. **J Pharm Sci** 1981 Jun;70(6):624-31

EPINEPHRINE

Central action of adrenaline. Jagiello-Wójtowicz E. **Acta Physiol Pol** 1981 Mar-Apr;32(2):169-80

Responses to catecholamines and nerve stimulation of the perfused rete tibiotarsale and associated blood vessels in the hind limb of the Mallard (Anas platyrhynchos). Midtgård U, et al. **Acta Physiol Scand** 1981 May; 112(1):77-81

Use of endotracheally administered epinephrine in a pediatric patient. Greenberg MI, et al. **Am J Dis Child** 1981 Aug;135(8):767-8

Catecholamine excretion rates in relation to life-styles in the male population of Otmoor, Oxfordshire. Reynolds V, et al. **Ann Hum Biol** 1981 May-Jun;8(3):197-209

Antidiuretic effects of intracerebroventricular infusion of adrenaline in conscious goats. Vendeputte-van Messom G, et al. **Arch Int Pharmacodyn Ther** 1981 Mar;250(1):137-46

Different sedimentation properties of agonist- and antagonist-labelled platelet alpha 2 adrenergic receptors. Michel T, et al. **Biochem Biophys Res Commun** 1981 Jun 16;100(3):1131-6

The effects of epinephrine on guinea pig placental glycogen metabolism and on cellular cyclic AMP. Sezer Yarimağan H, et al. **Biochem Med** 1981 Apr;25(2):125-34

Habitual catecholamine excretion and its relation to habitual distress. Forsman L. **Biol Psychol** 1980 Sep;11(2):83-97

ADP and epinephrine-induced release of platelet fibrinogen. Kaplan KL, et al. **Blood** 1981 Oct;58(4):797-802

Changes in plasma catecholamine concentrations during endotracheal intubation. Russell WJ, et al. **Br J Anaesth** 1981 Aug;53(8):837-9

The response of individual sympathetic preganglionic neurones to microelectrophoretically applied endogenous monoamines. Coote JH, et al. **Brain Res** 1981 Jun 29;215(1-2):135-45

Effects of an epinephrine synthesis inhibitor, SKF64139, on the secretion of luteinizing hormone in ovariectomized female rats. Crowley WR, et al. **Brain Res** 1981 Jan 5;204(1):231-5

Release of endogenous catecholamines from slices of hypothalamus of rats. Hamlet MA, et al. **Brain Res** 1981 Aug 3;217(2):315-25

High resolution radioautography of central dopaminergic fibers labelled in vitro with [3H]dopamine or [3H]norepinephrine. Nguyen-Legros J, et al. **Brain Res** 1981 Jun 1;213(2):265-76

Catecholamines and 5-hydroxytryptamine in photophores of Porichthys notatus. Radioenzymatic detection and radioautographic localization. Anctil M, et al. **Cell Tissue Res** 1981;219(3):557-66

Correlative light-, fluorescence- and electron-microscopic studies of catecholamine-storing cells in the adrenal medulla of the domestic fowl. Chungsamarnyart N, et al. **Cell Tissue Res** 1981;217(3):471-7

Catecholamine-storing cells in the adrenal medulla of the pre- and postnatal rat. Acetylcholinesterase as a means for early discrimination of cell types. Millar TJ, et al. **Cell Tissue Res** 1981;217(1):155-70

Total circulatory capacity in the rat. Effects of epinephrine and vasopressin on compliance and unstressed volume. Trippodo NC. **Circ Res** 1981 Oct;49(4):923-31

Influence of adrenal epinephrine on postnatal development of tyrosine hydroxylase activity in the superior cervical ganglion. Markey KA, et al. **Dev Neurosci** 1981;4(4):267-72

Direct phosphorylation effects of epinephrine on the plasma membranes of intact rat fat cells. Kang ES, et al. **Dev Pharmacol Ther** 1981; 2(1):55-66

Inhibitory effect of prostaglandins on the stimulation by glucagon and adrenaline of formation of cyclic AMP in rat hepatocytes. Brønstad GO, et al. **Eur J Biochem** 1981 Jul;117(2):369-74

Epinephrine as a potent releaser of immunoreactive beta-endorphin in rats. Berkenbosch F, et al. **Eur J Pharmacol** 1981 Jun 10; 72(1):97-100

The effects of topically applied epinephrine and timolol on intraocular pressure and aqueous humor cyclic-AMP in the rabbit. Boas RO, et al. **Exp Eye Res** 1981 Jun;32(6):681-90

Effects of epinephrine on plasma fibrinogen levels in rats submitted to tissue injury. Palma JA, et al. **Experientia** 1981 Jul 15;37(7):780-2

Role of ovarian hormones in the long-term control of glucose homeostasis. Interaction with insulin, glucagon and epinephrine. Ahmed-Sorour H, et al. **Horm Res** 1980;13(6):396-403

In vitro methylation of chromosomal proteins of the brain of rats of various ages & its modulation by epinephrine. Das R, et al. **Indian J Biochem Biophys** 1980 Dec;17(6):429-31

Effects of epinephrine and norepinephrine infusion on lung fluid balance in sheep. Minnear FL, et al. **J Appl Physiol** 1981 Jun;50(6):1353-7

A new method of administering aqueous epinephrine: the EpiPen, an automatic syringe. Lockey SD. **J Asthma Res** 1980 Jul;17(4):153-5

The invagination complex in nerve endings on adrenomedullary adrenaline cells: quantitative ultrastructural description, and analysis of changes with time-of-day and their modification by sham-surgery and pinealectomy. Kachi T, et al. **J Auton Nerv Syst** 1980 Oct; 2(3):241-58

The relation of plasma norepinephrine and epinephrine levels over time in humans. Levin BE, et al. **J Auton Nerv Syst** 1980 Dec; 2(4):315-25

Further studies of hormone-sensitive sodium and potassium transport in red cells from developing chick embryos. Shanbaky NM, et al. **J Cell Physiol** 1981 May;107(2):303-8

Effect of gonadectomy on the concentrations of catecholamines in discrete areas of the diencephalon of the domestic fowl. Knight PG, et al. **J Endocrinol** 1981 Jun;89(3):389-97

Biochemical variability in a tem sports situation. Biersner RJ, et al. **J Human Stress** 1981 Sep;7(3):12-7

Catecholamine and cortisol excretion patterns in three-year-old children and their parents. Lundberg U, et al. **J Human Stress** 1981 Sep; 7(3):3-11

Mechanism of the age-related decrease of epinephrine-stimulated lipolysis in isolated rat adipocytes: beta-adrenergic receptor binding, adenylate cyclase activity, and cyclic AMP accumulation. Dax EM, et al. **J Lipid Res** 1981 Aug;22(6):934-43

Emergency treatment of insect sting reactions -- should adrenaline be available in schools and camps? Wray BB, et al. **J Med Assoc Ga** 1981 Aug;70(8):551-2

Inhibitors of phenylethanolamine N-methyltransferase and epinephrine biosynthesis. 3. Bis[tetrahydroisoquinoline]s. DeMarinis RM, et al. **J Med Chem** 1981 Jun;24(6):756-9

High-performance liquid chromatography with electrochemical detection as a highly efficient tool for studying catecholaminergic systems. I. Quantification of noradrenaline, adrenaline and dopamine in cultured adrenal medullary cells. Müller TH, et al. **J Neurosci Methods** 1981 Jun;4(1):39-52

A kinetic analysis of the effects of adrenaline on calcium distribution in isolated rat liver parenchymal cells. Barritt GJ, et al. **J Physiol (Lond)** 1981 Mar;312:29-55

The effect of adrenaline and noradrenaline on coronary vascular reserve in the dog. Creates MS, et al. **J Physiol (Lond)** 1980 Dec; 309:557-68

Note on estimating catecholamines in urine sampled after 75-min periods of mental work and inactivity. Forsman L. **J Psychosom Res** 1981; 25(3):223-5

The effect of catecholamines or sodium lactate on blood lactate distribution in the rat. Aragno R. **J Sports Med Phys Fitness** 1981 Mar; 21(1):7-14

Propranolol and epinephrine [letter] Stotter ML. **JAMA** 1981 Oct 16; 246(16):1772

Adrenaline activation of phosphofructokinase in rat heart mediated by alpha-receptor mechanism independent of cyclic AMP. Clark MG, et al. **Nature** 1981 Jul 30;292(5822):461-3

Two different biophases for adrenaline released by electrical stimulation or tyramine from the sympathetic nerve endings of the dog saphenous vein. Guimarães S, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jun;316(3):200-4

Adrenal medullary secretory response to pontine and mesencephalic stimulation in the rat. Matsui H. **Neuroendocrinology** 1981 Aug; 33(2):84-7

Augmentation of thoracic duct lymph flow induced by adrenaline in the rabbits treated previously with propranolol. Toyosawa K, et al. **Nippon Seirigaku Zasshi** 1981;43(2):44-5

Carnitine optical isomers' action on the epinephrine stress induced in the isolated perfused rabbit heart. Fanelli O, et al. **Pharmacology** 1981; 22(6):371-7

Effect of epinephrine on prostaglandin E2 and cyclic AMP levels in gingiva of patients with chronic periodontitis. ElAttar TM, et al. **Prostaglandins Med** 1981 Jun;6(6):601-12

Low dose aspirin, platelet function and prostaglandin synthesis: influence of epinephrine and alpha adrenergic blockade. Rao GH, et al. **Prostaglandins Med** 1981 May;6(5):485-94

Relationships between sex-related psychological characteristics during adolescence and catecholamine excretion during achievement stress. Rauste-von Wright M, et al. **Psychophysiology** 1981 Jul;18(4):362-70

Epidurography using epinephrine and tomography. Easterbrook JS, et al. **Radiology** 1981 Sep;140(3):709-11

Changes of urinary kallikrein and kinin excretions induced by adrenalin infusion in conscious dogs. Olsen UB. **Scand J Clin Lab Invest** 1980 Apr;40(2):173-8

Effect of acetylcholine and catecholamines on the enterochromaffin-like cells of the stomach. Sano M, et al. **Surg Gynecol Obstet** 1981 Sep; 153(3):337-40

Responses of rabbit platelets to adrenaline induced by other agonists. Hallam TJ, et al. **Thromb Res** 1981 Feb-Mar;21(4-5):413-24

Effect of dexamethasone and epinephrine on metallothionein level in the perfused rat liver. Lee HS, et al. **Yonsei Med J** 1980;21(1):18-23

[Effect of pressure and local adrenaline application on carotid sinus on the perfusion pressure in the perfused hindlimb] Staak R. **Acta Biol Med Ger** 1981;40(2):189-99 (Eng. Abstr.) **(Ger)**

[Exercise-induced platelet aggregation: in vitro and ex-vivo aggregation of human platelets after administration of crystalline adrenaline and after ergometric exercise (author's transl)] Rieger H, et al. **Dtsch Med Wochenschr** 1981 Jul 17;106(29-30):942-5 (Eng. Abstr.) **(Ger)**

[Plasma catecholamines, metabolic substrates, aerobic and anaerobic capacity during graduated treadmill and bicycle ergometer exercise (author's transl)] Lehmann M, et al. **Klin Wochenschr** 1981 Jun 1; 59(11):553-9 (Eng. Abstr.) (Ger)

[The glycoregulatory response to glucagon and epinephrine infusions in chronic uremia] Perez G, et al. **Minerva Nefrol** 1979 Jul-Sep; 26(3):349-52 (Eng. Abstr.) (Ita)

[Effects of dipivalyl epinephrine and S-596, a new beta-adrenergic blocker, on human aqueous humor dynamics (author's transl)] Araie M, et al. **Nippon Ganka Gakkai Zasshi** 1981 May 10;85(5):349-54 (Eng. Abstr.) (Jpn)

[Effects of tetragastrin on catecholamines in gastric juice and gastric tissues in rats (author's transl)] Baba M, et al. **Nippon Shokakibyo Gakkai Zasshi** 1981 Jun;78(6):1191-7 (Eng. Abstr.) (Jpn)

[Adrenaline and noradrenaline levels before and after heart catheterization] Rumiński W, et al. **Pol Tyg Lek** 1981 Mar 30; 36(13):461-3 (Eng. Abstr.) (Pol)

[Plasma catecholamines of August and Wistar strain rats subjected to emotional stress] Kvetnanskii R, et al. **Fiziol Zh SSSR** 1981 Apr; 67(4):516-23 (Eng. Abstr.) (Rus)

ESCAPE REACTION

Social housing conditions influence escape deficits produced by uncontrollable stress: assessment of the contribution of norepinephrine. Anisman H, et al. **Behav Neural Biol** 1981 Aug;32(4):406-27

Cholinergic influences on escape deficits produced by uncontrollable stress. Anisman H, et al. **Psychopharmacology (Berlin)** 1981; 74(1):81-7

ESTRADIOL

Effect of oestrogen on the responsiveness of the pituitary gland to LRH: the role of corpora lutea. Koiter TR, et al. **Acta Endocrinol (Copenh)** 1981 Sep;98(1):29-35

Effect of oestradiol-17 beta on the metabolism of noradrenaline in brain slices of ovariectomized rats. Köster G, et al. **Acta Endocrinol (Copenh)** 1981 Sep;98(1):1-7

A different distribution of corticotropin releasing factor and arginine vasopressin contents in the hypothalamic nuclei after estrogen administration. Hashimoto K, et al. **Acta Med Okayama** 1981 Feb; 35(1):37-43

Induction of pseudo-pregnancy in Saccobranchus fossilis and cytomorphological assay of anomalies. Saxena V, et al. **Biochem Exp Biol** 1980;16(3):257-60

Temporal relationship between the abortifacient effects of GnRH antagonists and hormonal secretion. Rivier C, et al. **Biol Reprod** 1981 Jun;24(5):1061-7

Effects of estradiol and progesterone on plasma gonadotropins, prolactin, and LHRH in specific brain areas of ovariectomized rats. Wise PM, et al. **Biol Reprod** 1981 May;24(4):820-30

Effects of ageing and gonadal steroid hormones on prolactin concentrations in the anterior pituitary of the chicken. Kono T, et al. **Br Poult Sci** 1980 Nov;21(6):431-6

Differential effects of gonadal steroids on dopamine metabolism in mesolimbic and nigro-striatal pathways of male rat brain. Alderson LM, et al. **Brain Res** 1981 Aug 10;218(1-2):189-206

Differential effects of estrogen and androgen on locomotor activity induced in castrated male rats by amphetamine, a novel environment, or apomorphine. Menniti FS, et al. **Brain Res** 1981 Jul 6; 216(1):89-107

The effects of stimulation and lesion of raphe nuclei on luteinizing hormone release in estrogen-progesterone-treated ovariectomized rats. Waloch M, et al. **Brain Res** 1981 Aug 3;217(2):305-13

Persistence of dihydrotestosterone inhibition of lordosis in estrogen-primed rats fed a tryptophan-deficient diet. Menniti FS, et al. **Brain Res Bull** 1981 Jul;7(1):1-4

Oestrogen-gonadotrophin feedback mechanisms in the puerperium. Glass MR, et al. **Clin Endocrinol (Oxf)** 1981 Mar;14(3):257-67

Electrical stimulation of mesencephalic noradrenergic pathway: effects on luteinizing hormone levels in blood of ovariectomized and ovariectomized, steroid-primed rats. Leung PC, et al. **Endocrinology** 1981 Sep;109(3):720-8

Estrogen facilitation of lordosis behavior in the female rat. Gorski RA, et al. **Exp Brain Res** 1981;Suppl 3:222-37

Estradiol concentration in dopamine-beta-hydroxylase containing neurons of lower brain stem demonstrated by combined autoradiography and immunohistochemistry. Sar M, et al. **Exp Brain Res** 1981; Suppl 3:29-36

Role of ovarian hormones in the long-term control of glucose homeostasis. Interaction with insulin, glucagon and epinephrine. Ahmed-Sorour H, et al. **Horm Res** 1980;13(6):396-403

Effects of oestradiol, hypothalamic extracts and luteinizing hormone releasing hormone on rat anterior pituitary gland gonadotrophin release in vitro before and after the preovulatory luteinizing hormone surge at pro-oestrus. Elias KA, et al. **J Endocrinol** 1981 Sep;90(3):345-54

2-hydroxyoestradiol inhibits prolactin release from the superfused rat pituitary gland. Linton EA, et al. **J Endocrinol** 1981 Sep; 90(3):315-22

The failure of prolactin to enhance the inhibitory effect of oestradiol-17 beta on LH synthesis and release in ewes. Wright PJ, et al. **J Reprod Fertil** 1981 Jul;62(2):537-42

Effect of estradiol benzoate and clomiphene on tyrosine hydroxylase activity and on luteinizing hormone and prolactin levels in ovariectomized rats. Tobias H, et al. **Life Sci** 1981 Aug 17; 29(7):711-6

Uterine serotonin and receptor blockade during estrogen-induced uterine hyperemia. Van Orden DE, et al. **Proc Soc Exp Biol Med** 1981 Sep; 167(4):469-74

[Biological and immunological activity similar to digitalis glycosides of synthetic ACTH and some sex hormone 14-hydroxyderivatives (author's transl)] Schreiber V, et al. **Cas Lek Cesk** 1981 May 21; 120(20):616-8 (Eng. Abstr.) (Cze)

[Changes of hypothalamic LH-RH content induced by estradiol injection into female rats (author's transl)] Saito A. **Nippon Sanka Fujinka Gakkai Zasshi** 1981 Aug;33(8):1227-34 (Eng. Abstr.) (Jpn)

[Reaction between steroid hormones, the liver and its plasma membrane] Denisov IuP, et al. **Biull Eksp Biol Med** 1981 Jun;91(6):722-5 (Eng. Abstr.) (Rus)

EUPHORIA

[Effect of euphorigenic drugs on emotionally-positive brain systems] Zvartau EE, et al. **Zh Vyssh Nerv Deiat** 1981;31(2):308-14 (Eng. Abstr.) (Rus)

EXPLORATORY BEHAVIOR

Comparison of the effects of beta-endorphin and morphine on exploratory and socio-sexual behaviour in the male rat. Meyerson BJ. **Eur J Pharmacol** 1981 Feb 19;69(4):453-63

Potentiation by Des-Tyr-gamma-endorphin on apomorphine-induced changes in rat open field behavior. Nickolson VJ. **Eur J Pharmacol** 1981 Jun 10;72(1):77-81

Locomotor activity, defecation score and corticosterone levels during an openfield exposure: a comparison among individually and group-housed rats, and genetically selected rat lines. Gentsch C, et al. **Physiol Behav** 1981 Jul;27(1):183-6

The locomotor and exploratory activities in rats after lesion of hippocampal pyramidal cells with kainic acid. Kleinrok Z, et al. **Pol J Pharmacol Pharm** 1980;32(5):625-37

Effects of a piperazine derivative piribedil, on exploration, locomotor activity and social behaviour in the rat. File SE. **Prog Neuropsychopharmacol** 1981;5(3):245-55

EXTINCTION (PSYCHOLOGY)

The temporal structure of motivation IV: A reexamination of extinction effects in intracranial reward. Katz RJ. **Behav Neural Biol** 1981 Jun; 32(2):191-200

Extinction of a conditioned taste aversion in young, mid-aged, and aged C57/BL6 mice. Springer AD, et al. **Behav Neural Biol** 1981 Jul; 32(3):282-94

The partial reinforcement extinction effect: influence of chlordiazepoxide in septal lesioned rats. Feldon J, et al. **Psychopharmacology (Berlin)** 1981; 74(3):280-9

FEAR

Long-term effect of pentobarbital anesthesia on neophobia in the rat. McGee R, et al. **Behav Neural Biol** 1981 Jul;32(3):376-9

The acute effect of p-chloroamphetamine on the retention of fear conditioning in the rat: evidence for a role of serotonin in memory consolidation. Archer T, et al. **Neurosci Lett** 1981 Aug 7; 25(1):75-81

FENFLURAMINE

Different action of 5-hydroxytryptamine (5-HT) uptake inhibitors on fenfluramine- but not p-chloramphetamine-induced hyperthermia in rats. Pawlowski L. **J Pharm Pharmacol** 1981 Aug;33(8):538-40

FLUPHENAZINE

Daytime variation in serum prolactin level in patients receiving oral and depot antipsychotic medication. Goode DJ, et al. **Biol Psychiatry** 1981 Jul;16(7):653-62

Fluphenazine resistant psychosis. Brent R, et al. **Can J Psychiatry** 1981 Mar;26(2):118-9

Appropriate treatment of fibromyositis [letter] Labowitz RJ, et al. **Del Med J** 1981 Aug;53(8):389

Oral fluphenazine and tea and coffee drinking [letter] Wallace SM, et al. **Lancet** 1981 Sep 26;2(8248):691

Effects of fluphenazine hydrochloride on the bone-marrow cells of Swiss mice. Rao KP, et al. **Mutat Res** 1981 Jul;89(3):237-40

Flupenthixol versus combined fluphenazine-nortriptyline in depressive illness. Conway JF. **Practitioner** 1981 Mar;225(1353):400-4

The prolactin response in patients receiving neuroleptic therapy. The effect of fluphenazine decanoate. Dotti A, et al. **Prog Neuropsychopharmacol** 1981;5(1):69-77

[Flufenazine decanoate in the ambulatory treatment of schizophrenic patients] Populin M, et al. **Minerva Psichiatr** 1981 Apr-Jun; 22(2):85-92 (73 ref.) (Eng. Abstr.) **(Ita)**

FLURAZEPAM

Determination of the major urinary metabolite of flurazepam in man by high-performance liquid chromatography. Weinfeld RE, et al. **J Chromatogr** 1981 Apr 10;223(1):123-30

Regional specificity of benzodiazepine receptor down-regulation during chronic treatment of rats with flurazepam. Rosenberg HC, et al. **Neurosci Lett** 1981 Jun 12;24(1):49-52

Dose-related effects of flurazepam on human sleep-walking patterns. Karacan I, et al. **Psychopharmacology (Berlin)** 1981;73(4):332-9

FOOD DEPRIVATION

Rewarding effect of noradrenergic stimulation of the amygdala in food deprived rats. Jurkowlaniec E, et al. **Physiol Behav** 1981 Jul; 27(1):27-31

FSH

Direct effects of gonadotropin releasing hormone and its antagonist upon ovarian functions stimulated by FSH, prolactin, ans LH. Jones PB, et al. **Biol Reprod** 1981 May;24(4):747-59

Site of action of prolactin in the suppression of gonadotropin secretion during lactation in the rat: effect on pituitary responsiveness to LHRH. Smith MS. **Biol Reprod** 1981 Jun;24(5):967-76

The presence of two species of follicle-stimulating hormone within hamster anterior pituitary glands as disclosed by concanavalin A chromatography. Chappel SC. **Endocrinology** 1981 Sep;109(3):935-42

Frequency and amplitude of gonadotropin-releasing hormone stimulation and gonadotropin secretion in the rhesus monkey. Wildt L, et al. **Endocrinology** 1981 Aug;109(2):376-85

Influence of neonatal ovariectomy on the developmental patterns of serum gonadotropins, hypothalamic LH-RH concentration and organ weights in female rats. Döcke F, et al. **Endokrinologie** 1981 Mar; 77(3):273-85

Differential effects of testosterone and its metabolites on gonadotrophin secretion in the intact adult male rat. Reymond M, et al. **Horm Res** 1981;14(2):114-29

Multihormonal regulation of ornithine decarboxylase activity in highly differentiated porcine granulosa cells in vitro. Veldhuis JD, et al. **J Cell Physiol** 1981 Aug;108(2):213-20

Effects of oestradiol, hypothalamic extracts and luteinizing hormone releasing hormone on rat anterior pituitary gland gonadotrophin release in vitro before and after the preovulatory luteinizing hormone surge at pro-oestrus. Elias KA, et al. **J Endocrinol** 1981 Sep;90(3):345-54

Repetitive treatment with gonadotrophin releasing factor or a long-acting analogue upon gonadotrophin secretion in the ferret. Gledhill B, et al. **J Endocrinol** 1981 Aug;90(2):275-83

Time-related secretion of gonadotrophins after a single injection of steroid-free bovine follicular fluid in prepubertal and adult female rats. Hermans WP, et al. **J Endocrinol** 1981 Jul;90(1):69-76

Dissociation in the regulation of luteinizing hormone and follicle-stimulating hormone in a hyperprolactinaemic rat model: interrelationships between gonadotrophin and prolactin control. Tresguerres JA, et al. **J Endocrinol** 1981 Jul;90(1):41-51

Modulation of FSH-controlled steroidogenesis in rat granulosa cells: direct in-vitro effects of LHRH and ICI-118630. Hillier SG, et al. **Mol Cell Endocrinol** 1981 Aug;23(2):193-205

Hormonal regulation of cytodifferentiation and intercellular communication in cultured granulosa cells. Amsterdam A, et al. **Proc Natl Acad Sci USA** 1981 May;78(5):3000-4

[Intracellular mechanism for the action of inhibin on the secretion of the follicular-stimulating hormone and luteinizing hormone induced by LH-RH in vitro] Lecomte-Yerna MJ, et al. **C R Trav Lab Carlsberg** 1981;175(3):385-8 (Eng. Abstr.) **(Fre)**

[Effect of gonadotropin releasing hormone, clomide and L-dopa on the secretion of chorionic gonadotropins, follicle-stimulating hormone and prolactin in the first trimester of uncomplicated pregnancy] Rzempoluch J. **Ginekol Pol** 1981 Jan;52(2):211-4 **(Pol)**

GABA

Dextro-phenylalanine as inhibitor of the noradrenaline release from the isolated rat hypothalamus. Pardal JF, et al. **Acta Neurol Latinoam** 1979; 25(3-4):235-48

Role of GABA-ergic receptors for the synthesis of GABA in different compartments of the rat cerebellum. Carmona E, et al. **Acta Physiol Scand** 1981 May;112(1):109-10

Opposing actions of convulsants and anticonvulsants on GABA responses of crayfish stretch receptors. Adams PR, et al. **Adv Biochem Psychopharmacol** 1981;29:369-78

Opposite effects of 5,5-diphenylhydantoin and picrotoxin on GABAergic inhibition in crayfish stretch receptor. Aickin CC, et al. **Adv Biochem Psychopharmacol** 1981;29:301-7

Depolarizing postsynaptic actions of GABA in the rat dentate gyrus. Assaf SY, et al. **Adv Biochem Psychopharmacol** 1981;29:239-48

Actions of GABA on mammalian neurones, axons, and nerve terminals. Brown DA, et al. **Adv Biochem Psychopharmacol** 1981;29:321-6 (33 ref.)

Enzymology of the alternative reductive pathway of GABA catabolism leading to the biosynthesis of gamma-hydroxybutyrate. Cash CD, et al. **Adv Biochem Psychopharmacol** 1981;29:527-35 (31 ref.)

Development of GABA-accumulating neurons and glial cells in the rat visual cortex. Chronwall BM, et al. **Adv Biochem Psychopharmacol** 1981; 29:453-8

GABA and muscimol binding processes in CNS tissue culture preparations. DeFeudis FV, et al. **Adv Biochem Psychopharmacol** 1981; 29:405-10

Physiological study of amino acid uptake and receptor desensitization: the GABA system in dorsal root ganglia. Désarménien M, et al. **Adv Biochem Psychopharmacol** 1981;29:309-19

Effects of GABA metabolism on [3H]-GABA transport in synaptosomal preparations from rat cerebral cortex. Gardner CR, et al. **Adv Biochem Psychopharmacol** 1981;29:143-50

In vivo release of newly synthesized GABA in the basal ganglia of the cat. Gauchy C, et al. **Adv Biochem Psychopharmacol** 1981;29:183-91

GABA systems and behavior. Koella WP. **Adv Biochem Psychopharmacol** 1981;29:11-21 (32 ref.)

Comparison of the uptake processes of taurine, hypotaurine, and GABA. Kontro P. **Adv Biochem Psychopharmacol** 1981;29:161-7

Action of GABA on hippocampal neurons. Krnjević K. **Adv Biochem Psychopharmacol** 1981;29:231-7

THIP, isoguvacine, isoguvacine oxide, and related GABA agonists. Krogsgaard-Larsen P, et al. **Adv Biochem Psychopharmacol** 1981; 29:69-76 (31 ref.)

The neurohypophysial GABA system. Mathison RD, et al. **Adv Biochem Psychopharmacol** 1981;29:343-50 (23 ref.)

Autoradiographic and immunocytochemical evidence for the existence of GABAergic neurons in the nucleus raphe dorsalis--possible existence of neurons containing 5HT and glutamate decarboxylase. Nanopoulos D, et al. **Adv Biochem Psychopharmacol** 1981;29:519-25

Potassium-stimulated release of taurine, hypotaurine, and GABA from brain tissue in vitro. Oja SS, et al. **Adv Biochem Psychopharmacol** 1981; 29:175-81

Roles of GABA and glycine in the substantia nigra. Pycock CJ, et al. **Adv Biochem Psychopharmacol** 1981;29:77-87 (52 ref.)

GABA binding to dendrodendritic synaptosomal membranes from rat olfactory bulbs. Quinn MR, et al. **Adv Biochem Psychopharmacol** 1981; 29:421-8

GABA and its interaction with ACh in the rabbit retina. Redburn DA, et al. **Adv Biochem Psychopharmacol** 1981;29:169-74

Heterocyclic GABA analogues as selective inhibitors of astroglial GABA uptake. Schousboe A, et al. **Adv Biochem Psychopharmacol** 1981; 29:135-41 (28 ref.)

Release of endogenous GABA from the rat brain: methodological aspects and the effects of catecholamines. van der Heyden JA, et al. **Adv Biochem Psychopharmacol** 1981;29:193-203

Evidence for a dual role of GABA as a synaptic transmitter and a promoter of synaptogenesis. Wolff JR. **Adv Biochem Psychopharmacol** 1981;29:459-65 (29 ref.)

CSF GABA in normal subjects and patients with depression, schizophrenia, mania, and anorexia nervosa. Gerner RH, et al. **Am J Psychiatry** 1981 Aug;138(8):1098-101

Effect of histamine H1- and H2-receptor agonists on gamma-aminobutyric acid (GABA) content in hypothalamus and striatum of the rat brain. Nowak JZ, et al. **Arch Immunol Ther Exp (Warsz)** 1980;28(6):917-20

Effects of gamma-acetylenic GABA and gamma-vinyl GABA on synaptosomal release and uptake of GABA. Abdul-Ghani AS, et al. **Biochem Pharmacol** 1981 Jun 1;30(11):1203-9

Pharmacological specificity of synaptosomal and synaptic membrane gamma-aminobutyric acid (GABA) transport processes. Early SL, et al. **Biochem Pharmacol** 1981 May 15;30(10):1105-13

Valproate induced changes in GABA metabolism at the subcellular level. Löscher W. **Biochem Pharmacol** 1981 Jun 1;30(11):1364-6

Efflux of gamma-aminobutyric acid by synaptic plasma membrane vesicles isolated from rat brain. Kanner BI, et al. **Biochemistry** 1981 Jun 9; 20(12):3354-8

Stimulation of benzodiazepine binding to rat brain membranes and solubilized receptor complex by avermectin B1a and gamma-aminobutyric acid. Pong SS, et al. **Biochim Biophys Acta** 1981 Aug 6;646(1):143-50

On the mechanism by which veratridine causes a calcium-independent release of gamma-aminobutyric acid from brain slices. Cunningham J, et al. **Br J Pharmacol** 1981 Jul;73(3):655-67

The effects of 4-aminopyridine on the isolated vas deferens and its effects on the inhibitory properties of adenosine, morphine, noradrenaline and gamma-aminobutyric acid. Stone TW. **Br J Pharmacol** 1981 Jul; 73(3):791-6

The dendritic response to GABA in CA1 of the hippocampal slice. Djørup A, et al. **Brain Res** 1981 Aug 24;219(1):196-201

Electrophysiological evidence favoring intracaudate axon collaterals of GABAergic caudate output neurons in the cat. Katayama Y, et al. **Brain Res** 1981 Jul 6;216(1):180-6

GABA and muscimol open ion channels of different lifetimes on cultured mouse spinal cord cells. Mathers DA, et al. **Brain Res** 1981 Jan 5; 204(1):242-7

Alteration of GABA system in frog retina following short light and dark adaptations - a quantitative comparison with retinal taurine. Nishimura C, et al. **Brain Res** 1981 Aug 31;219(2):433-8

Ultrastructure of GABA-neurons in cultures of rat neostriatum. Panula P, et al. **Brain Res** 1981 Aug 24;219(1):202-7

Ethyl beta-carboline-3-carboxylate antagonizes the action of GABA and benzodiazepines in the hippocampus. Polc P, et al. **Brain Res** 1981 Jul 27;217(1):216-20

Benzodiazepine binding and interactions with the GABA receptor complex in living cultures of rat cerebral cortex. White WF, et al. **Brain Res** 1981 Jun 29;215(1-2):162-76

Postnatal changes of GABAergic and glutamatergic parameters. Wong PT, et al. **Brain Res** 1981 Jul;227(4):519-29

Biochemical development of the human brain. II. Some parameters of the GABA-ergic system. Brooksbank BW, et al. **Dev Neurosci** 1981; 4(3):188-200

Developmental changes of the GABA and polyamine systems in isolated neurons in cell culture. Seiler N, et al. **Dev Neurosci** 1981; 4(3):181-7

Increases and decreases in local cerebral glucose utilization in response to GABA agonists. Palacios JM, et al. **Eur J Pharmacol** 1981 May 8; 71(2-3):333-6

[3H] Ethyl beta-carboline-3-carboxylate binding to the benzodiazepine receptor is not affected by GABA. Patel J, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):419-20

Effect of aminooxyacetic acid on endogenous GABA release from rat retina. Mizuno A, et al. **Exp Eye Res** 1981 Aug;33(2):197-202

Transport and metabolism of glutamate and GABA in neurons are glial cells. Schousboe A. **Int Rev Neurobiol** 1981;22:1-45 (419 ref.)

Gamma-aminobutyric acid system in rat oviduct. Martin del Rio R. **J Biol Chem** 1981 Oct 10;256(19):9816-9

GABAergic synapses in the goldfish retina: an autoradiographic study of 3H-muscimol and 3H-GABA binding. Yazulla S. **J Comp Neurol** 1981 Jul 20;200(1):83-93

Concurrent acetylcholinesterase staining and gamma-aminobutyric acid uptake of cortical neurons in culture. Mesulam MM, et al. **J Histochem Cytochem** 1981 Feb;29(2):306-8

Selective inhibition of L-glutamate and gammaaminobutyrate transport in nerve ending particles by aluminium, manganese, and cadmium chloride. Wong PC, et al. **J Inorg Biochem** 1981 Jun;14(3):253-60

Epimeric cis-decahydroquinoline-5-carboxylic acids: effects on gamma-aminobutyric acid uptake and receptor binding in vitro. Witiak DT, et al. **J Med Chem** 1981 Jul;24(7):788-94

Release of 3H-gamma-aminobutyric acid (GABA) by inhibitory neurons of the crayfish. Craelius W, et al. **J Neurobiol** 1981 May; 12(3):249-58

Enhancement of depolarization-induced release of gamma-aminobutyric acid from brain slices by antibodies to ganglioside. Frieder B, et al. **J Neurochem** 1981 Sep;37(3):634-9

Characterization of the binding of the GABA agonist [3H]piperidine-4-sulphonic acid to bovine brain synaptic membranes. Krogsgaard-Larsen P, et al. **J Neurochem** 1981 Aug;37(2):401-9

Effects of sodium and bicarbonate ions on gamma-aminobutyric acid receptor binding in synaptic membranes of rat brain. Kurioka S, et al. **J Neurochem** 1981 Aug;37(2):418-21

Characterization of gamma-aminobutyric acid binding sites on crude synaptic membranes. Kurioka S, et al. **J Neurochem** 1981 Aug; 37(2):283-8

Glutamate as a putative transmitter in the cerebellum: stimulation by GABA of glutamic acid release from specific pools. Levi G, et al. **J Neurochem** 1981 Jul;37(1):22-31

Effect of inhibitors of GABA aminotransferase on the metabolism of GABA in brain tissue and synaptosomal fractions. Löscher W. **J Neurochem** 1981 Apr;36(4):1521-7

gamma-Aminobutyric acid concentration in cerebrospinal fluid in schizophrenia. McCarthy BW, et al. **J Neurochem** 1981 Apr; 36(4):1406-8

GABA-benzodiazepine-barbiturate receptor interactions. Olsen RW. **J Neurochem** 1981 Jul;37(1):1-13 (146 ref.)

Elevation of brain GABA content by chronic low-dosage administration of hydrazine, a metabolite of isoniazid. Perry TL, et al. **J Neurochem** 1981 Jul;37(1):32-9

Sulfur amino acid metabolism in the developing rhesus monkey brain: subcellular studies of taurine, cysteinesulfinic acid decarboxylase, gamma-aminobutyric acid, and glutamic acid decarboxylase. Rassin DK, et al. **J Neurochem** 1981 Sep;37(3):740-8

Topographical distribution of gamma-aminobutyric acid within the cat thalamus in relation to the basal ganglia, as determined by mass fragmentometry. Yoshida M, et al. **J Neurochem** 1981 Sep; 37(3):670-6

Sizes and distributions of intrinsic neurons incorporating tritiated GABA in monkey sensory-motor cortex. Hendry SH, et al. **J Neurosci** 1981 Apr;1(4):390-408

Characterization of benzodiazepine and gamma-aminobutyric recognition sites and their endogenous modulators. Massotti M, et al. **J Neurosci** 1981 Apr;1(4):409-18

Different efficacies of d- and l-gamma-amino-beta-hydroxybutyric acids in GABA receptor and transport test systems. Roberts E, et al. **J Neurosci** 1981 Feb;1(2):132-40

Effect of GABAergic drugs on dopamine catabolism in the nigrostriatal and mesolimbic dopaminergic pathways of the rat. Gundlach AL, et al. **J Pharm Pharmacol** 1981 Jan;33(1):41-3

Reductions in retinal gamma-aminobutyric acid (GABA) content and in [3H]flunitrazepam binding after postnatal monosodium glutamate injections in rats. Regan JW, et al. **J Pharmacol Exp Ther** 1981 Sep; 218(3):791-6

Two kinds of recurrent inhibition of cat spinal alpha-motoneurones as differentiated pharmacologically. Cullheim S, et al. **J Physiol (Lond)** 1981 Mar;312:209-24

GABA-antagonists and spatial summation in Y-type cat retinal ganglion cells. Kirby AW, et al. **J Physiol (Lond)** 1981 Mar;312:335-44

The how of anxiety [editorial] **Lancet** 1981 Aug 1;2(8240):237-9

Neurochemical studies in the hypoxic brain: substance P, met-enkephalin, GABA and angiotensin converting enzyme. Arregui A, et al. **Life Sci** 1981 Jun 29;28(26):2925-9

Intracerebral injection of gamma vinyl GABA: method for measuring rates of GABA synthesis in specific brain regions in vivo. Casu M, et al. **Life Sci** 1981 Aug 17;29(7):681-8

Increased gamma-aminobutyric acid (GABA), homocarnosine and beta-alanine in cerebrospinal fluid of patients treated with gamma-vinyl GABA (4-amino-hex-5-enoic acid). Grove J, et al. **Life Sci** 1981 May 21;28(21):2431-9

Supersensitivity of substantia nigra pars reticulata neurons to GABAergic drugs after striatal lesions. Waszczak BL, et al. **Life Sci** 1981 May 21; 28(21):2411-20

GABA transport in the rat thyroid. Gebauer H. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Aug;317(1):61-6

Comparison between (RS)-nipecotic acid and GABA transport in cultured astrocytes: coupling with two sodium ions. Larsson OM, et al. **Neurochem Res** 1981 Mar;6(3):257-66

Studies on the release of exogenous and endogenous GABA and glutamate from rat brain synaptosomes. Levi G, et al. **Neurochem Res** 1981 Mar; 6(3):275-85

Endogenous inhibitors of Na+-independent [3H]GABA binding to crude synaptic membranes. Massotti M, et al. **Neurochem Res** 1981 May; 6(5):551-65

Comparison of synaptosomal and glial uptake of pipecolic acid and GABA in rat brain. Nomura Y, et al. **Neurochem Res** 1981 Apr; 6(4):391-400

gamma-Aminobutyric acid system in isolated dorsal and ventral horn neurons from bovine spinal cord. Wakabayashi M, et al. **Neurochem Res** 1981 Jun;6(6):659-71

The in vitro iontophoretic release of radiolabelled histamine, N'-methylhistamine and GABA from 7-barrelled glass micropipettes. Roberts F. **Neuropharmacology** 1981 Jul;20(7):711-4

GABA receptors distribution in rat substantia nigra. De Montis GM, et al. **Neurosci Lett** 1981 May 29;23(3):257-61

Direct action of pentobarbitone in potentiating the responses to GABA of rat dorsal root ganglion neurones in vitro. Headley PM, et al. **Neurosci Lett** 1981 Jul 17;24(3):273-80

Autoradiographic localization of [3H]gamma-amino-butyric acid in the myenteric plexus of the guinea-pig small intestine. Krantis A, et al. **Neurosci Lett** 1981 May 29;23(3):263-8

Bilateral asymmetry in brain GABA function? Starr MS, et al. **Neurosci Lett** 1981 Sep 1;25(2):167-72

Septal driving of hippocampal theta rhythm: a role for gamma-aminobutyrate in the effects of minor tranquilizers? Mellanby J, et al. **Neuroscience** 1981;6(7):1412-21

Distribution of gamma-aminobutyrate in the rat thalamus: specific decreases in thalamic gamma-aminobutyrate following lesion or electrical stimulation of the substantia nigra. Starr MS, et al. **Neuroscience** 1981;6(6):1095-104

Effect of kainic acid on ultrastructure and gamma-aminobutyrate-related circuits in the optic tectum of the goldfish. Villani L, et al. **Neuroscience** 1981;6(7):1393-403

Effect of combined treatment with dopaminergic and GABA-ergic drugs on the threshold for maximal electroconvulsions in mice. Czuczwar SJ. **Pol J Pharmacol Pharm** 1981 Jan-Feb;33(1):25-35

Colonic bacteria: a source of gamma-aminobutyric acid in blood. Schafer

DF, et al. **Proc Soc Exp Biol Med** 1981 Jul;167(3):301-3

A dual role for GABA in quasi-morphine abstinence behavior induced by di-n-propylacetate involving both initiation and termination. Van der Laan JW, et al. **Psychopharmacology (Berlin)** 1981;74(2):143-8

Hindbrain GABA receptors influence parasympathetic outflow to the stomach. Williford DJ, et al. **Science** 1981 Oct 9;214(4517):193-4

[Influence of the GABAergic system on eating behavior induced by the tail pinching technic in rats] Bereksi B, et al. **C R Trav Lab Carlsberg** 1981;175(3):323-9 (Eng. Abstr.) **(Fre)**

[GABA containing neurons in the nucleus raphes dorsalis of the rat (author's transl)] Pfister C, et al. **Acta Histochem (Jena)** 1981; 68(1):117-24 (Eng. Abstr.) **(Ger)**

[GABA fluophore formation due to ninhydrin reaction in the octanolic milieu. Fluorescence histochemical investigation. 3. Information (author's transl)] Pfister C, et al. **Acta Histochem (Jena)** 1981; 68(2):231-7 (Eng. Abstr.) **(Ger)**

[Influence of the central dopaminergic system on GABAergic activity of the cerebellum. Preliminary results] Di Giorgio RM, et al. **Acta Neurol [Quad] (Napoli)** 1981;42:302-4 (Eng. Abstr.) **(Ita)**

[Pharmacological influences on the brain level and transport of GABA. II) Effect of various psychoactive drugs on brain level and uptake of GABA] Gabana MA, et al. **Boll Soc Ital Biol Sper** 1981 Apr 30; 57(8):909-13 (Eng. Abstr.) **(Ita)**

[Pharmacological influences on the brain level and transport of GABA. I) Effect of various antipileptic drugs on brain levels of GABA] Varotto M, et al. **Boll Soc Ital Biol Sper** 1981 Apr 30;57(8):904-8 (Eng. Abstr.) **(Ita)**

[Effect of GABA-negative preparations on the anxiolytic and sedative effects of diazepam] Andreev BV, et al. **Biull Eksp Biol Med** 1981 Jun; 91(6):685-7 (Eng. Abstr.) **(Rus)**

[Nipecotic acid, a competitive inhibitor of the net uptake of 3H-GABA by rat brain synaptosomes] Kovalev GI, et al. **Biull Eksp Biol Med** 1981 Jun;91(6):692-4 (Eng. Abstr.) **(Rus)**

[GABA-ergic correlates of aggression and intraspecies sociability of mice subjected to isolation] Poshivalov VP. **Biull Eksp Biol Med** 1981 May; 91(5):584-7 (Eng. Abstr.) **(Rus)**

[New evidence for a GABA-ergic component in the mechanism of action of benzodiazepine tranquilizers] Zakusov VV, et al. **Biull Eksp Biol Med** 1981 May;91(5):571-4 (Eng. Abstr.) **(Rus)**

[A case of aminalon-induced disease] Bondarenko BB, et al. **Klin Med (Mosk)** 1981 Mar;59(3):109-10 **(Rus)**

GALVANIC SKIN RESPONSE

Bilateral skin conductance, finger pulse volume, and EEG orienting response to tones of differing intensities in chronic schizophrenics and controls. Bernstein AS, et al. **J Nerv Ment Dis** 1981 Aug; 169(8):513-28

Effects of exogenous stimuli and centrally acting drugs on galvanic skin responses in rats. Hata T, et al. **Jpn J Pharmacol** 1981 Feb; 31(1):23-31

GLUCURONIDASE

Comparative studies of asparagine-linked oligosaccharide structures of rat liver microsomal and lysosomal beta-glucuronidases. Mizuochi T, et al. **Arch Biochem Biophys** 1981 Jun;209(1):298-303

Disassociation of lysosomal enzyme secretion and macrophage-mediated bone resorption. Blair H, et al. **Biochem Biophys Res Commun** 1981 Jun 16;100(3):959-64

On the enzymatic hydrolysis of the sulfate conjugate of 3-methoxy-4-hydroxyphenylglycol (MHPG). Karoum F, et al. **Biochem Med** 1980 Dec;24(3):314-20

Beta-glucuronidase activity in Enterobacteriaceae. Massenti MF, et al. **Boll Ist Sieroter Milan** 1981;60(1):26-30

On-line cleavage of urinary estriol conjugates with immobilized beta-glucuronidase before liquid-chromatographic analysis. Bowers LD, et al. **Clin Chem** 1981 Sep;27(9):1554-7

Influence of age and sex on five human plasma lysosomal enzymes assayed by automated procedures. Lombardo A, et al. **Clin Chim Acta** 1981 Jun 18;113(2):141-52

The inhibition of PMN beta-glucuronidase release by Aroclor 1254. Lee TP. **Environ Res** 1981 Aug;25(2):386-90

The effects of testosterone and progestins on the rate of beta-glucuronidase synthesis in mouse kidney as studied with an immunoprecipitation assay. Gupta C, et al. **Int J Androl** 1981 Jun; 4(3):342-54

Acid hydrolases in the epididymis of normal, castrated, vasectomized, cryptorchid and cryptepididymal rats. Mayorga LS, et al. **Int J Androl** 1981 APr;4(2):208-19

Changes of sulfated mucopolysaccharides and mucopolysaccharidases during fetal development. Sampaio LO, et al. **J Biol Chem** 1981 Sep 10;256(17):9205-10

Turnover of two lysosomal enzymes in macrophages. Skudlarek MD, et al. **J Biol Chem** 1981 Oct 10;256(19):10137-44

Pulmonary alveolar macrophage lysosomal enzyme activity after sublethal rotational trauma. Starling JR, et al. **J Surg Res** 1981 Aug; 31(2):128-35

Increase of beta-glucuronidase activity in the serum of rats administered organophosphate and carbamate insecticides. Kikuchi H, et al. **J Toxicol Sci** 1981 Feb;6(1):27-35

Effect of organic thio-compounds on detoxication of glucuronyltransferase and beta-glucuronidase in the rat liver. Tamura S, et al. **J Toxicol Sci** 1981 Feb;6(1):19-16

Inhibitory effect of bile acids on the activity of human beta-glucuronidase at its optimal pH. Ho KJ, et al. **Proc Soc Exp Biol Med** 1981 Jul; 167(3):304-9

Circadian changes of lysosomal enzyme activities in rat hepatocytes using ultracytochemistry. Uchiyama Y, et al. **Prog Clin Biol Res** 1981; 59C(00):117-24

Histochemical evidence for radiation enhancement of lysosomal response following hyperthermia of tail cartilage in baby rat. Myers R, et al. **Radiat Res** 1981 Aug;87(2):329-40

[Histochemical demonstration of beta-glucuronidase and leucine aminopeptidase in cultivated aortic endothelial cells (author's transl)] Halle W, et al. **Acta Histochem (Jena)** 1981;68(2):188-92 (Eng. Abstr.) **(Ger)**

[Biochemical studies on acidic glycosaminoglycans in gingiva and dental pulp. 4. Beta-glucuronidase activity in dental pulp (author's transl)] Sakamoto N, et al. **Hiroshima Daigaku Shigaku Zasshi** 1980; 12(2):265-70 **(Jpn)**

GONADOTROPINS, PITUITARY

Gonadotrophin release by gonadotrophs incubated with gonadotrophin-releasing hormone is independent of intracellular cAMP accumulation. Benoist L, et al. **Acta Endocrinol (Copenh)** 1981; 97(3):329-37

Long lasting amplification and deformation of thyroid receptors after thyrotropin (TSH) and gonadotropin (GTH) treatment of chickens in the foetal period. Nagy SU, et al. **Acta Physiol Acad Sci Hung** 1980; 56(3):303-7

On the correlation of luteinizing hormone-releasing hormone, luteinizing hormone, follicle-stimulating hormone, and prolactin levels in plasma of women with normal menstrual cycles. Aksel S. **Am J Obstet Gynecol** 1981 Oct 15;141(4):362-7

Effect of 20 alpha-dihydroprogesterone, progesterone, and their 5 alpha-reduced metabolites on serum gonadotropin levels and hypothalamic LHRH content. Gilies PA, et al. **Biol Reprod** 1981 Jun; 24(5):1088-97

Effects of estradiol and progesterone on plasma gonadotropins, prolactin, and LHRH in specific brain areas of ovariectomized rats. Wise PM, et al. **Biol Reprod** 1981 May;24(4):820-30

Oestrogen-gonadotrophin feedback mechanisms in the puerperium. Glass MR, et al. **Clin Endocrinol (Oxf)** 1981 Mar;14(3):257-67

Steroid effects on hypothalamic-gonadotropin interactions. McCann SM, et al. **Exp Brain Res** 1981;Suppl 3:142-50

Differences in negative and positive feedback of gonadal steroids on release of gonadotropins and prolactin in young and old rats. Meites J, et al. **Exp Brain Res** 1981;Suppl 3:151-7

GUANETHIDINE

Adrenergic blocking agents inadequate for nonsurgical male contraception. Alexander NJ, et al. **Fertil Steril** 1981 Jul; 36(1):119-21

[Effect of phenoxybenzamine on the adrenergic neurone blocking action of guanethidine in isolated guinea pig vas deferens (author's transl)] Kontani H. **Yakugaku Zasshi** 1980 Dec;100(12):1247-51 (Eng. Abstr.) **(Jpn)**

HABITUATION (PSYCHOPHYSIOLOGY)

Mathematical model of synaptic plasticity: II. Habituation. Lara R, et al. **Neurol Res** 1980;2(1):1-18

HALOPERIDOL

Hazards of mistaking haloperidol for diazepam [letter] Nininger JE, et al. **Am J Psychiatry** 1981 Aug;138(8):1130

An analysis of the effects of apomorphine and haloperidol on the release of [3H]-dopamine and [3H]-noradrenaline from rabbit brain slices. Kelly MJ. **Arch Int Pharmacodyn Ther** 1981 Mar;250(1):18-29

Effect of haloperidol withdrawal on motor activity and circadian rhythm of rats. Kumar A, et al. **Arzneimittelforsch** 1981;31(7):1096-8

Disrupted latent inhibition in the rat with chronic amphetamine or haloperidol-induced supersensitivity: relationship to schizophrenic attention disorder. Solomon PR, et al. **Biol Psychiatry** 1981 Jun; 16(6):519-37

Total and free serum haloperidol levels in schizophrenic patients and the effect of age thioridazine and fatty acid on haloperidol-serum protein binding in vitro. Rowell FJ, et al. **Br J Clin Pharmacol** 1981 Apr; 11(4):377-82

Increase in mesolimbic electrical self-stimulation after chronic

haloperidol: reversal by L-DOPA or lithium. Seeger TF, et al. **Brain Res** 1981 Jun 29;215(1-2):404-9
Promethazine and diazepam potantiate the haloperidol induced prolactin responses. Arató M. **Commun Psychopharmacol** 1980;4(4):317-22
In normal young men acute dopaminergic blockade does not impair free water excretion following a standard water load. Cohen M, et al. **Commun Psychopharmacol** 1980;4(4):323-6
Apomorphine, haloperidol and the average evoked potentials in normal human volunteers. Rey AC, et al. **Commun Psychopharmacol** 1980; 4(4):327-34
Apomorphine-induced stereotypy in matuse and senescent rats following cessation of chronic haloperidol treatment. Roffman M, et al. **Commun Psychopharmacol** 1980;4(4):283-6
Brain contribution to the haloperidol-induced increase in plasma homovanillic acid. Kendler KS, et al. **Eur J Pharmacol** 1981 May 8; 71(2-3):321-6
Antagonizing effects of haloperidol and bicuculline on inhibition of neurons of the substantia nigra, pars compacta. Nakamura S, et al. **Exp Neurol** 1981 Jul;73(1):304-9
Pituitary response to luteinizing hormone-releasing hormone during haloperidol-induced hyperprolactinemia. Del Carmen Díaz M, et al. **Fertil Steril** 1981 Jun;35(6):626-8
Isolation and identification of a metabolite of haloperidol. Pape BE. **J Anal Toxicol** 1981 May-Jun;5(3):113-7
High-performance liquid chromatographic determination of haloperidol in plasma. Miyazaki K, et al. **J Chromatogr** 1981 May 8; 223(2):449-53
Alterations of immune reactivity by haloperidol and delta-9-tetrahydrocannabinol. Levy JA, et al. **J Immunopharmacol** 1981; 3(1):93-109
Identification and distribution of neuroleptic binding sites in the rat spinal cord. Demenge P, et al. **J Neurochem** 1981 Jul;37(1):53-9
Haloperidol-induced reduction of nigral substance P-like immunoreactivity: a probe for the interactions between dopamine and substance P neuronal systems. Hanson GR, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):568-74
Effects of haloperidol and pimozide on classical conditioning of the rabbit nictitating membrane response. Harvey JA, et al. **J Pharmacol Exp Ther** 1981 Sep;218(3):712-9
Effects of short- and long-term neuroleptic treatment on brain serotonin synthesis and turnover: focus on the serotonin hypothesis of schizophrenia. Rastogi RB, et al. **Life Sci** 1981 Aug 17;29(7):735-41
Prolonged adverse effects of haloperidol in normal subjects [letter] Anderson BG, et al. **N Engl J Med** 1981 Sep 10;305(11):643-4
Illicit haldol [letter] Kruesi M, et al. **N Engl J Med** 1981 Sep 24; 305(13):769
Modulation by dopamine antagonists of DNA synthesis in the pituitary gland of the male rat. Jacobi JM, et al. **Neuroendocrinology** 1981 Aug; 33(2):97-100
A double-blind comparison of bromperidol and haloperidol in newly admitted schizophrenic patients. Brannen JO, et al. **Pharmacopsychiatria** 1981 Jul;14(4):139-40
A multicenter controlled trial in phobic-obsessive psychoneurosis. The effect of chlorimipramine and of its combinations with haloperidol and diazepam. Cassano GB, et al. **Prog Neuropsychopharmacol** 1981; 5(2):129-38
Chronic haloperidol treatment fails to alter the anorexic actions of dopaminergic agonists and cholinergic drugs. Hynes MD, et al. **Prog Neuropsychopharmacol** 1981;5(3):271-5
Enduring behavioural and biochemical effects in the adult rat after prolonged postnatal administration of haloperidol. Cuomo V, et al. **Psychopharmacology (Berlin)** 1981;74(2):166-9
Effects of chronic haloperidol treatment on ingestive behaviour and body weight regulation in the rat. Uguru-Okorie DC. **Psychopharmacology (Berlin)** 1981;73(4):384-7
The effects of haloperidol on the EEG spectrum. Wieneke GH, et al. **Psychopharmacology (Berlin)** 1981;74(1):33-4
[Toxicity of organic phosphates under the influence of neuroleptics] Andreas K, et al. **Acta Biol Med Ger** 1980;39(8-9):987-9 **(Ger)**
[Influence of the central dopaminergic system on GABAergic activity of the cerebellum. Preliminary results] Di Giorgio RM, et al. **Acta Neurol [Quad] (Napoli)** 1981;42:302-4 (Eng. Abstr.) **(Ita)**
[Pharmacological influences on the brain level and transport of GABA. II) Effect of various psychoactive drugs on brain level and uptake of GABA] Gabana MA, et al. **Boll Soc Ital Biol Sper** 1981 Apr 30; 57(8):909-13 (Eng. Abstr.) **(Ita)**

HANDLING (PSYCHOLOGY)

Stressor effects of handling on the immature fowl. Freeman BM, et al. **Res Vet Sci** 1979 Mar;26(2):223-6

HEXOBARBITAL

Effect of diethyldithiocarbamate on the metabolic elimination of hexobarbital, phenazone, tolbutamide and four halogenated hydrocarbons. Siegers CP, et al. **Eur J Drug Metab Pharmacokinet** 1981; 6(2):141-8
Heme enhances hexobarbital metabolism in perfused rat liver after drug-mediated destruction of cytochrome P-450. Farrell GC, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):363-7
Interaction of lithium and disulfiram in hexobarbital hypnosis: possible role of the 5-HT system. Minegishi A, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):481-7
[The effect of noise on the biotransformation of hexobarbital in the rat] Loertzer HJ, et al. **Z Gesamte Hyg** 1981;27(6):438-40 (Eng. Abstr.) **(Ger)**
[Development of hexobarbital radiometry and its application (author's transl)] Inoue K, et al. **Eisei Shikenjo Hokoku** 1980;98:56-62 (Eng. Abstr.) **(Jpn)**
[Inhibition of bacterial luminescence by cytochrome P-450 substrates] Ismailov AD, et al. **Biokhimiia** 1981 Feb;46(2):234-9 (Eng. Abstr.) **(Rus)**
[Mechanism of pantogam potentiation of certain effects of hexobarbital and sodium barbital and inhibition of phenamine hyperactivity] Avakumov VM, et al. **Farmakol Toksikol** 1981 Jan-Feb;44(1):30-4 (Eng. Abstr.) **(Rus)**

HISTAMINE

Pharmacological investigations into the effects of histamine and histamine analogs on guinea pig and rat uterus. Goyal RK, et al. **Agents Actions** 1981 Jul;11(4):312-7
The importance of human intestinal diamine oxidase in the oxidation of histamine and/or putrescine. Biegański T, et al. **Arch Immunol Ther Exp (Warsz)** 1980;28(6):901-6
Influence of oxotremorine on histamine level and histamine synthesis in the rat brain. Bielkiewicz B, et al. **Arch Immunol Ther Exp (Warsz)** 1980;28(6):921-5
Effects of mianserin, desipramine and maprotiline on blood pressure responses evoked by acetylcholine, histamine and 5-hydroxytryptamine in rats. Cavero I, et al. **Br J Pharmacol** 1981 Sep;74(1):143-8
Reactivity of isolated trachea, bronchus and lung strip of cats of carbachol, 5-hydroxytryptamine and histamine: evidence for the existence of methysergide-sensitive receptors. Chand N. **Br J Pharmacol** 1981 Aug; 73(4):853-7
Effects of chemical transmitters on function of isolated canine parietal cells. Soll AH, et al. **Fed Proc** 1981 Aug;40(10):2519-23
Mechanism of histamine-induced excitation of the cat pylorus. Biancani P, et al. **J Clin Invest** 1981 Sep;68(3):582-8
Snake alpha-toxin effects on cholinergic and noncholinergic responses of Aplysia californica neurons. Ono JK, et al. **J Neurosci** 1981 Mar; 1(3):259-70
Cholinergic and alpha adrenergic augmentation of histamine-induced contraction of canine airway smooth muscle. Leff AR, et al. **J Pharmacol Exp Ther** 1981 Sep;218(3):582-7
The in vitro iontophoretic release of radiolabelled histamine, N'-methylhistamine and GABA from 7-barrelled glass micropipettes. Roberts F. **Neuropharmacology** 1981 Jul;20(7):711-4
[Blood and skin histamine and serotonin levels in rats following second degree burns] Nowik-Jurek M, et al. **Pol Tyg Lek** 1981 May 4; 36(18):631-5 (Eng. Abstr.) **(Pol)**
[Effect of various pharmacologic preparations on the viability of Chinese hamster fibroblasts in vitro] Beuverova EI, et al. **Biull Eksp Biol Med** 1981 Jun;91(6):739-40 (Eng. Abstr.) **(Rus)**
[Effect of disturbance of the liver and myocardium innervation on the histamine and serotonin contents in their tissues] Aksenova VM. **Ukr Biokhim Zh** 1980 Sep-Oct;52(5):569-72 (Eng. Abstr.) **(Rus)**

HOSTILITY

Changes in the hostility of schizophrenic patients during treatment. Tsiantis J, et al. **Br J Med Psychol** 1981 Sep;54(Pt 3):251-8
Hostility conflict and the effect of chlordiazepoxide on change in hostility level. Downing RW, et al. **Compr Psychiatry** 1981 Jul-Aug; 22(4):362-7

HYDANTOINS

Induction of drug-metabolizing enzymes by the enantiomers of normephenytoin in the rat. James R, et al. **Drug Metab Dispos** 1981 May-Jun;9(3):297-302
Mesantoin (methoin) [letter] Buckroyd JE. **Med J Aust** 1981 Apr 18; 1(8):431

HYDRAZINES

Effects of benserazide and carbidopa on the metabolism of L-tryptophan by isolated rat liver cells. Smith SA, et al. **Biochem Pharmacol** 1981 Mar 15;30(6):623-8
Toxic and teratogenic effects of hydrazine on fathead minnow (pimephales promelas) embryos. Henderson V, et al. **Arch Environ Contam Toxicol** 1981 Jun;26(6):807-12
Elevation of brain GABA content by chronic low-dosage administration

of hydrazine, a metabolite of isoniazid. Perry TL, et al. **J Neurochem** 1981 Jul;37(1):32–9

Metabolism of isoniazid and free hydrazine formation in isolated rat hepatocytes. Hirata M, et al. **J Pharmacobiodyn** 1981 Feb;4(2):145–7

[Effect of hydrazine sulfate on lipid composition in rat liver homogenates and plasma membranes] Nechiporuk TS, et al. **Ukr Biokhim Zh** 1980 Sep–Oct;52(5):636–42 (Eng. Abstr.) **(Rus)**

HYDRAZONES

Identification of hydrazone of norethindrone, a metabolic product resulting from the interaction between isoniazid and norethindrone. Watanabe H, et al. **Res Commun Chem Pathol Pharmacol** 1981 Mar; 31(3):435–42

[Research on substances with antiviral activity. XVIII. Bis–amidinohydrazones of N–heterocyclic aromatic dialdehydes] Garuti L, et al. **Farmaco [Sci]** 1981 Jun;36(6):393–9 (Eng. Abstr.) **(Ita)**

HYDROXYBUTYRATES

Enzymology of the alternative reductive pathway of GABA catabolism leading to the biosynthesis of gamma–hydroxybutyrate. Cash CD, et al. **Adv Biochem Psychopharmacol** 1981;29:527–35 (31 ref.)

Influence of ration composition and energy balance on blood beta–hydroxybutyrate (ketone) and plasma glucose concentrations of dairy cows in early lactation. Herdt TH, et al. **Am J Vet Res** 1981 Jul;42(7):1177–80

The influence of sodium gamma–hydroxybutyrate on GABA receptors and catecholamine effect potentiation. Kozhechkin SN. **Arch Int Pharmacodyn Ther** 1981 Apr;250(2):242–53

Metabolism of L–and D–3–hydroxybutyrate by rat liver during development. Swiatek KR, et al. **Biochem Med** 1981 Apr; 25(2):160–7

Ontogeny of gamma–hydroxybutyric acid. I. Regional concentration in developing rat, monkey and human brain. Snead OC 3d, et al. **Brain Res** 1981 Jul;227(4):579–89

Glucose and 3–hydroxybutyrate utilization by chick telencephalon during postnatal development. Nehlig A, et al. **Experientia** 1981 Jun; 37(6):553–5

Electrocorticographic activity induced by gamma hydroxybutyrate in the rat during ontogenesis. Rokyta R, et al. **Experientia** 1981 Jul 15; 37(7):750–2

Blood concentration and disappearance of injected alanine and beta–hydroxybutyrate in surgical patients. Swaminathan R, et al. **Horm Metab Res** 1981 Jul;13(7):383–6

Energy metabolism in rat brain: inhibition of pyruvate decarboxylation by 3–hydroxybutyrate in neonatal mitochondria. Booth RF, et al. **J Neurochem** 1981 Jul;37(1):179–85

Regional and subcellular localization in rat brain of the enzymes that can synthesize gamma–hydroxybutyric acid. Rumigny JF, et al. **J Neurochem** 1981 Apr;36(4):1433–8

Gamma–hydroxybutyrate treatment of schizophrenia: a pilot study. Schulz SC, et al. **Pharmacopsychiatria** 1981 Jul;14(4):129–34

[Effect of sodium hydroxybutyrate on mitochondrial oxidative phosphorylation and myocardial pentose cycle enzymes during high altitude hypoxia] Chotoev ZhA, et al. **Farmakol Toksikol** 1981 Mar–Apr; 44(2):159–62 (Eng. Abstr.) **(Rus)**

[Effect of certain GABA–ergic substances on dopamine metabolism in the rat brain] Malikova LA, et al. **Farmakol Toksikol** 1981 Jan–Feb; 44(1):37–40 (Eng. Abstr.) **(Rus)**

HYDROXYDOPAMINES

Effect of neonatal administrations of 6–OHDA on the brain development. I. Alteration in the striatum. Imamoto K, et al. **Arch Histol Jpn** 1980 Oct;43(4):347–64

Conspecific odor preferences of male albino rats are reversed by intracerebral 6–hydroxydopamine. Cornwell–Jones CA. **Brain Res** 1981 Jun 1;213(2):379–85

Behavioural recovery following transplantation of substantia nigra in rats subjected to 6–OHDA lesions of the nigrostriatal pathway. I. Unilateral lesions. Dunnett SB, et al. **Brain Res** 1981 Jun 29;215(1–2):147–61

Presynaptic alpha–adrenergic mediation of self–stimulation in locus coeruleus in rats treated neonatally with 6–hydroxydopamine. Umemoto M, et al. **Brain Res** 1981 Aug 24;219(1):107–19

Changes in brain norepinephrine content in mice following neonatal 6–hydroxydopamine. Lovell KL. **Brain Res Bull** 1981 Jul;7(1):41–4

Effect of dopamine agonists and antagonists on the electrical activity of substantia nigra neurons transplanted into the lateral ventricle of the rat. Wuerthele SM, et al. **Exp Brain Res** 1981;44(1):1–10

6–Hydroxydopamine and radiofrequency lesions of the lateral entorhinal cortex facilitate an operant appetitive conditioning task in mice. Gauthier M, et al. **Neurosci Lett** 1981 Jul 2;24(2):193–7

Effects of 6–hydroxydopamine lesions of locus coeruleus on startle in rats. Adams LM, et al. **Psychopharmacology (Berlin)** 1981; 73(4):394–8

HYDROXYINDOLEACETIC ACID

Cerebrospinal fluid amine metabolites, tryptophan and clinical parameters in depression. Part 1. Background variables. Banki CM, et al. **J Affective Disord** 1981 Jun;3(2):81–9

Postmortem changes of 5–hydroxytryptamine and 5–hydroxyindoleacetic acid in mouse brain and their prevention by pargyline and microwave irradiation. Van Wijk M, et al. **Neurochem Res** 1981 Apr; 6(4):425–30

[Metabolism of peripheral catecholamines and indole amines in healthy persons. Clinico–biochemical correlates] Krzyżowski J, et al. **Pol Tyg Lek** 1981 Mar 16;36(11):417–21 (Eng. Abstr.) **(Pol)**

[Interstrain differences in the serotonin and 5–hydroxyindoleacetic acid levels in the postnatal ontogeny of C57BL/6J and BALB/cLac strain mice] Lobacheva II, et al. **Ontogenez** 1981;12(3):306–10 (Eng. Abstr.) **(Rus)**

HYDROXYTRYPTOPHAN

Effect of 5–hydroxytryptophan on electrocortical activity and breathing movements of fetal sheep. Quilligan EJ, et al. **Am J Obstet Gynecol** 1981 Oct 1;141(3):271–5

Inverse relation of substance P–like immunoreactivity in dorsal raphe nucleus to serotonin levels in pons–medulla following administration of cocaine and 5–hydroxytryptophan. Pradhan S, et al. **Biochem Pharmacol** 1981 May 15;30(10):1071–6

Rapid and simple analysis of DOPA and 5–HTP using high performance liquid chromatography with electrochemical detection. Arnerić SP, et al. **Brain Res Bull** 1981 May;6(5):407–11

Monoamine precursor uptake in ganglia of a mollusc Anodonta cygnea L. (Bivalvia) An autoradiographic and ultrastructural study. Elekes K. **Cell Tissue Res** 1981;219(2):403–15

Elevation of 3,4–dihydroxyphenylacetic acid concentration by L–5–hydroxytryptophan in control and fluoxetine–pretreated rats. Fuller RW, et al. **J Pharm Pharmacol** 1981 Jun;33(6):406–7

Backward walking induced by L–5–hydroxytryptophan in mice. Shimomura K, et al. **Jpn J Pharmacol** 1981 Feb;31(1):39–46

Radioautographic study of uptake and storage of indoleamines in the rabbit enterochromaffin cells. Mourre C, et al. **Neurosci Lett** 1981 May 29;23(3):251–6

Effects of serotonin and L–5–hydroxytryptophan on plasma renin activity in rats. Barney CC, et al. **Pharmacol Biochem Behav** 1981 Jun; 14(6):895–900

Peripheral conversion of L–5–hydroxytryptophan to serotonin induces drinking in rats. Kikta DC, et al. **Pharmacol Biochem Behav** 1981 Jun; 14(6):889–93

Supersensitivity to L–5–hydroxytryptophan after 5,7–dihydroxytryptamine injections in desmethylimipramine– and nomifensine–pretreated rats: behavioral evidence for postsynaptic supersensitivity. Ortmann R, et al. **Psychopharmacology (Berlin)** 1981; 74(2):109–14

HYDROXYZINE

Simultaneous determination of hydroxyzine hydrochloride and benzyl alcohol in injection solutions by high–performance liquid chromatography. Menon GN, et al. **J Pharm Sci** 1981 Jun; 70(6):697–8

HYPERKINESIS

Suction lesions of the frontal cerebral cortex in the rat induce asymmetrical behavioral and catecholaminergic responses. Pearlson GD, et al. **Brain Res** 1981 Aug 10;218(1–2):233–42

HYPERKINETIC SYNDROME

L–dopa and treatment of hyperactive children. Knobel M, et al. **Acta Paedopsychiatr (Basel)** 1981 May;47(1):27–31

Tryptophan metabolism in children with attentional deficit disorder. Irwin M, et al. **Am J Psychiatry** 1981 Aug;138(8):1082–5

Treatment alternatives for hyperactive children – a comment on 'problem children' and stimulant drug treatment. Glow RA. **Aust NZ J Psychiatry** 1981 Jun;15(2):123–8

'Problem children' and stimulant drug treatment. Prior M. **Aust NZ J Psychiatry** 1981 Jun;15(2):117–21

Saccades of hyperactive and normal boys during ocular pursuit. Bala SP, et al. **Dev Med Child Neurol** 1981 Jun;23(3):323–36

The hyperactive child in adolescence: some pharmacologic approaches. White JH. **J Adolesc** 1981 Mar;4(1):79–86

Optimal dosages of methylphenidate for improving the learning and behavior of hyperactive children. Charles L, et al. **JDBP** 1981 Sep; 2(3):78–81

HYSTERIA

[Feasibility of pathogenetic therapy for hysteria] Semke VIa.

Zh Nevropatol Psikhiatr 1981;81(3):420-5 (Eng. Abstr.) (Rus)

IMIPRAMINE

A comparison of phenelzine and imipramine in an obsessive-compulsive patient. Isberg RS. **Am J Psychiatry** 1981 Sep;138(9):1250-1

Cognitive dysfunction and imipramine in outpatient depressive. Glass RM, et al. **Arch Gen Psychiatry** 1981 Sep;38(9):1048-51

Prophylactic lithium carbonate with and without imipramine for bipolar I patients. A double-blind study. Quitkin FM, et al. **Arch Gen Psychiatry** 1981 Aug;38(8):902-7

Interaction of imipramine with the ionic channel of the acetylcholine receptor of motor endplate and electric organ. Eldefrawi ME, et al. **Biochem Pharmacol** 1981 Jun 1;30(11):1391-4

Plasma concentration monitoring of hydroxylated metabolites of imipramine and desipramine. DeVane CL, et al. **Drug Intell Clin Pharm** 1981 Apr;15(4):263-6

Species and dose differences in the accumulation of imipramine by mammalian lungs. Drew R, et al. **Drug Metab Dispos** 1981 Jul-Aug; 9(4):322-6

Sodium dependency of [3H]imipramine binding in rat cerebral cortex. Briley M, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):377-80

Absence of high-ffinity [3H]imipramine binding in platelets and cerebral cortex of fawn-hooded rats. Dumbrille-Ross A, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):137-8

Differential sensitivity to the effects of psychotropic drugs: psychotics vs normals; Asian vs Western populations. Okuma T. **Folia Psychiatr Neurol Jpn** 1981;35(1):79-87

Selective inhibitory effects of chlorpromazine and imipramine on platelet aggregation. Ishigooka J, et al. **Int Pharmacopsychiatry** 1980; 15(5):270-80

Differential effects of cognitive therapy and pharmacotherapy on depressive symptoms. Rush AJ, et al. **J Affective Disord** 1981 Sep; 3(3):221-9

Distribution of specific high-affinity binding sites for [3H]imipramine in human brain. Langer SZ, et al. **J Neurochem** 1981 Aug;37(2):267-71

Localisation of tricyclic antidepressant binding sites on serotonin nerve terminals. Sette M, et al. **J Neurochem** 1981 Jul;37(1):40-2

Simultaneous determination of imipramine, desipramine, and their 2-hydroxy metabolites in plasma by ion-pair reversed-phase high-performance liquid chromatography with amperometric detection. Suckow RF, et al. **J Pharm Sci** 1981 Mar;70(3):257-61

The effect of single and chronic administration of imipramine on clonidine-induced hypothermia in the rat. Górka Z, et al. **Life Sci** 1981 Jun 22;28(25):2847-54

Does high affinity [3H] imipramine binding label serotonin reuptake sites in brain and platelet? Paul SM, et al. **Life Sci** 1981 Jun 15; 28(24):2753-60

CSF-MHPG in depressive syndromes: basal values and imipramine-induced modifications. Roccatagliata G, et al. **Neuropsychobiology** 1981;7(4):169-71

Further studies on a novel animal model of depression: therapeutic effects of a tricyclic antidepressant. Roth KA, et al. **Neurosci Biobehav Rev** 1981 Summer;5(2):253-8

The effect of imipramine and mianserin on the behavior and EEG afterdischarges induced by single electric stimulation of the rabbit amygdala. Ossowska K, et al. **Pol J Pharmacol Pharm** 1980 Jul-Aug; 32(4):513-22

The effect of multiple imipramine administration on monoaminergic systems of the rat brain. Vetulani J, et al. **Pol J Pharmacol Pharm** 1980 Jul-Aug;32(4):523-30

The effect of multiple rising doses of Ro 11-2465 (serotonin uptake inhibitor) on serotonin content of human platelets. Lenehan T, et al. **Psychopharmacology (Berlin)** 1981;74(1):1-3

Effect of imipramine on high potassium evoked 3H-dopamine release in the rat striatum. Kamiya H, et al. **Res Commun Chem Pathol Pharmacol** 1981 Jul;33(1):49-60

INHIBITION (PSYCHOLOGY)

Disrupted latent inhibition in the rat with chronic amphetamine or haloperidol-induced supersensitivity: relationship to schizophrenic attention disorder. Solomon PR, et al. **Biol Psychiatry** 1981 Jun; 16(6):519-37

[Physiopathology of inhibition and proposals for an original therapeutic response] Laborit H. **Agressologie** 1981;22(2):45-53 (90 ref.) (Eng. Abstr.) **(Fre)**

LACTATES

Stimulation of rat renal phosphoenolpyruvate carboxykinase activity after an intravenous lactic acid load. Vargas AM, et al. **FEBS Lett** 1981 May 5;127(1):121-4

The effect of catecholamines or sodium lactate on blood lactate distribution in the rat. Aragno R. **J Sports Med Phys Fitness** 1981 Mar; 21(1):7-14

LEARNING

Modifications of the dopaminergic receptors sensitivity and learning of normoxic or hypobaric hypoxic rats. Saligaut C, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):80-7

A new approach to the role of noradrenaline in learning: problem-solving in the marmoset after alpha-noradrenergic receptor blockade. Ridley RM, et al. **Pharmacol Biochem Behav** 1981 Jun;14(6):849-55

The influence of fragments of the LPH chains on learning, memory and attention in animals and man. Sandman CA, et al. **Pharmacol Ther [B]** 1981;13(1):39-60 (76 ref.)

Post-learning paradoxical sleep, reticular activation and noradrenergic activity. Leconte P, et al. **Physiol Behav** 1981 Apr;26(4):587-94

[Improvement of post-training performance 4 weeks after stimulation of the locus coeruleus in rats : absence of an effect of a lesion of the dorsal noradrenergic bundle] Velley L, et al. **C R Acad Sci [D] (paris)** 1981 May 4;292(16):943-6 (Eng. Abstr.) **(Fre)**

LEVODOPA

L-dopa and treatment of hyperactive children. Knobel M, et al. **Acta Paedopsychiatr (Basel)** 1981 May;47(1):27-31

Decrease of vascular angiotensin sensitivity by L-dopa during human pregnancy. Kaulhausen H, et al. **Am J Obstet Gynecol** 1981 Jul 15; 140(6):671-5

Striatal dopamine turnover and L-dopa treatment after short-term exposure of rats to manganese. Shukla GS, et al. **Arch Toxicol** 1981 Jun;47(3):191-6

Aromatic L-amino acid decarboxylase activity in central and peripheral tissues and serum of rats with L-DOPA and L-5-hydroxytryptophan as substrates. Rahman MK, et al. **Biochem Pharmacol** 1981 Mar 15; 30(6):645-9

L-DOPA (L-3,4-dihydroxyphenylalanine) uptake by human red blood cells. Floud A, et al. **Biochim Biophys Acta** 1981 Jul 20; 645(2):165-9

Increase in mesolimbic electrical self-stimulation after chronic haloperidol: reversal by L-DOPA or lithium. Seeger TF, et al. **Brain Res** 1981 Jun 29;215(1-2):404-9

Induction of swimming in the high spinal stingray by L-DOPA. Williams BJ, et al. **Brain Res** 1981 Sep 7;220(1):208-13

Inhibition of the renin-angiotensin-aldosterone system by L-dopa with and without inhibition of extracerebral dopa decarboxylase in man. Barbieri C, et al. **Clin Sci** 1981 Aug;61(2):187-90

Effects of L-dopa on dopamine and norepinephrine concentrations in rat brain assessed by gas chromatography. Doshi PS, et al. **J Chromatogr** 1981 Jun 19;210(3):505-11

Dosage form design for improvement of bioavailability of levodopa IV: Possible causes of low bioavailability of oral levodopa in dogs. Sasahara K, et al. **J Pharm Sci** 1981 Jul;70(7):730-3

Antagonism of KW-5338 (domperidone) against emesis and depression of intestinal motility induced by L-DOPA. Shuto K, et al. **J Pharmacobiodyn** 1980 Dec;3(12):709-14

Pharmacological difference of L-dopa, apomorphine, and bromocriptine against metoclopramide. Fang VS. **Life Sci** 1981 May 11; 28(19):2143-9

Effect of L-dopa treatment on cerebral amino acid levels in rats after portocaval anastomosis. Zanchin G, et al. **Neurochem Res** 1981 Jun; 6(6):649-58

Synergistic induction of pineal gland N-acetyltransferase activity by amphetamine and L-DOPA. Altar A, et al. **Proc West Pharmacol Soc** 1981;24:101-4

[Effect of gonadotropin releasing hormone, clomide and L-dopa on the secretion of chorionic gonadotropins, follicle-stimulating hormone and prolactin in the first trimester of uncomplicated pregnancy] Rzempoluch J. **Ginekol Pol** 1981 Jan;52(2):211-4 **(Pol)**

[Effect of certain neuromediators on segmental mechanisms of vasomotor regulation] Zaitsev AA, et al. **Farmakol Toksikol** 1981 Mar-Apr; 44(2):178-81 (Eng. Abstr.) **(Rus)**

LH

Dopaminergic and adrenergic effects on plasma LH levels in rats with hypothalamic islands. van Dieten JA, et al. **Acta Endocrinol (Copenh)** 1981;97(3):289-96

Potentiation of prostaglandin E2-induced release of LH by the prostaglandin analogue, 7-oxa-13-prostynoic acid. Warberg J. **Acta Endocrinol (Copenh)** 1981;97(3):297-304

Hypothalamic-pituitary function in normal ewes and ewes which grazed oestrogenic subterranean clover for several years. Chamley WA, et al. **Aust J Biol Sci** 1981;34(2):239-44

Melatonin effect on the hamster pituitary response to LHRH. Bacon A, et al. **Biol Reprod** 1981 Jun;24(5):993-9

Direct effects of gonadotropin releasing hormone and its antagonist upon ovarian functions stimulated by FSH, prolactin, ans LH. Jones PB, et al. **Biol Reprod** 1981 May;24(4):747-59

Temporal relationship between the abortifacient effects of GnRH antagonists and hormonal secretion. Rivier C, et al. **Biol Reprod** 1981

Jun;24(5):1061-7

Site of action of prolactin in the suppression of gonadotropin secretion during lactation in the rat: effect on pituitary responsiveness to LHRH. Smith MS. **Biol Reprod** 1981 Jun;24(5):967-76

Lack of a relationship between concentrations of plasma luteinising hormone, thyroxine and prolactin at nine week's of age and subsequent egg production in the domestic hen. Sharp PJ, et al. **Br Poult Sci** 1981 Jan;22(1):53-8

Effects of an epinephrine synthesis inhibitor, SKF64139, on the secretion of luteinizing hormone in ovariectomized female rats. Crowley WR, et al. **Brain Res** 1981 Jan 5;204(1):231-5

Effect of manipulating central catecholamines on puberty and the surge of luteinizing hormone and gonadotropin releasing hormone induced by pregnant mare serum gonadotropin in female rats. Sarkar DK, et al. **Brain Res** 1981 Jun 1;213(2):335-49

The effects of stimulation and lesion of raphe nuclei on luteinizing hormone release in estrogen-progesterone-treated ovariectomized rats. Waloch M, et al. **Brain Res** 1981 Aug 3;217(2):305-13

Induction and maintenance of gonadotropin and lactogen receptors in hypoprolactinemic rats. Huhtaniemi IT, et al. **Endocrinology** 1981 Aug; 109(2):483-90

Electrical stimulation of mesencephalic noradrenergic pathway: effects on luteinizing hormone levels in blood of ovariectomized and ovariectomized, steroid-primed rats. Leung PC, et al. **Endocrinology** 1981 Sep;109(3):720-8

Endocrine correlates of sexual development in the male monkey, Macaca fascicularis. Steiner RA, et al. **Endocrinology** 1981 Sep;109(3):914-9

Frequency and amplitude of gonadotropin-releasing hormone stimulation and gonadotropin secretion in the rhesus monkey. Wildt L, et al. **Endocrinology** 1981 Aug;109(2):376-85

Influence of neonatal ovariectomy on the developmental patterns of serum gonadotropins, hypothalamic LH-RH concentration and organ weights in female rats. Döcke F, et al. **Endokrinologie** 1981 Mar; 77(3):273-85

Differential effects of testosterone and its metabolites on gonadotrophin secretion in the intact adult male rat. Reymond M, et al. **Horm Res** 1981;14(2):114-29

Role of thyroxine & gonadotropins on the mobilization of ovarian cholesterol in a teleost Anabas testudineus (Bloch). Sen S, et al. **Indian J Exp Biol** 1981 May;19(5):408-12

Multihormonal regulation of ornithine decarboxylase activity in highly differentiated porcine granulosa cells in vitro. Veldhuis JD, et al. **J Cell Physiol** 1981 Aug;108(2):213-20

Effects of oestradiol, hypothalamic extracts and luteinizing hormone releasing hormone on rat anterior pituitary gland gonadotrophin release in vitro before and after the preovulatory luteinizing hormone surge at pro-oestrus. Elias KA, et al. **J Endocrinol** 1981 Sep;90(3):345-54

Repetitive treatment with gonadotrophin releasing factor or a long-acting analogue upon gonadotrophin secretion in the ferret. Gledhill B, et al. **J Endocrinol** 1981 Aug;90(2):275-83

Time-related secretion of gonadotrophins after a single injection of steroid-free bovine follicular fluid in prepubertal and adult female rats. Hermans WP, et al. **J Endocrinol** 1981 Jul;90(1):69-76

Effect of gonadectomy on the concentrations of catecholamines in discrete areas of the diencephalon of the domestic fowl. Knight PG, et al. **J Endocrinol** 1981 Jun;89(3):389-97

Evidence that changes in luteinizing hormone secretion regulate the growth of the preovulatory follicle in the ewe. McNatty KP, et al. **J Endocrinol** 1981 Sep;90(3):375-89

Dissociation in the regulation of luteinizing hormone and follicle-stimulating hormone in a hyperprolactinaemic rat model: interrelationships between gonadotrophin and prolactin control. Tresguerres JA, et al. **J Endocrinol** 1981 Jul;90(1):41-51

Development of a quotidian increase in pituitary responsiveness to GnRH in prepubertal female rats. Wilkinson M, et al. **J Reprod Fertil** 1981 Jul;62(2):393-8

Prolactin and LH release in response to LH-RH and TRH in ewes during dioestrus, pregnancy and post partum. Wright PJ, et al. **J Reprod Fertil** 1981 Jul;62(2):447-53

The failure of prolactin to enhance the inhibitory effect of oestradiol-17 beta on LH synthesis and release in ewes. Wright PJ, et al. **J Reprod Fertil** 1981 Jul;62(2):537-42

Neuroendocrine effects of D,L-propranolol [letter] Malas KL, et al. **Lancet** 1981 Aug 22;2(8243):424

Effect of estradiol benzoate and clomiphene on tyrosine hydroxylase activity and on luteinizing hormone and prolactin levels in ovariectomized rats. Tobias H, et al. **Life Sci** 1981 Aug 17; 29(7):711-6

[Intracellular mechanism for the action of inhibin on the secretion of the follicular-stimulating hormone and luteinizing hormone induced by LH-RH in vitro] Lecomte-Yerna MJ, et al. **C R Trav Lab Carlsberg** 1981;175(3):385-8 (Eng. Abstr.) **(Fre)**

[Changes of hypothalamic LH-RH content induced by estradiol injection into female rats (author's transl)] Saito A. **Nippon Sanka Fujinka Gakkai Zasshi** 1981 Aug;33(8):1227-34 (Eng. Abstr.) **(Jpn)**

[Role of noradrenaline in luteinizing hormone secretion] Adamskaia El, et al. **Biull Eksp Biol Med** 1981 Jun;91(6):730-3 (Eng. Abstr.) **(Rus)**

[Role of noradrenaline-sensitive neurons of the preoptic area in regulating luteinizing hormone release] Babichev VN, et al. **Fiziol Zh SSSR** 198 Jun;67(6):809-15 (Eng. Abstr.) **(Rus)**

LH-FSH RELEASING HORMONE

Effect of oestrogen on the responsiveness of the pituitary gland to LRH: the role of corpora lutea. Koiter TR, et al. **Acta Endocrinol (Copenh)** 1981 Sep;98(1):29-35

Effect of a synthetic LH-RH agonist on the endocrine function of the testis, adrenocortex and thyroid gland in cocks. Pethes G, et al. **Acta Physiol Acad Sci Hung** 1980;56(3):281-7

On the correlation of luteinizing hormone-releasing hormone, luteinizing hormone, follicle-stimulating hormone, and prolactin levels in plasma of women with normal menstrual cycles. Aksel S. **Am J Obstet Gynecol** 1981 Oct 15;141(4):362-7

Handling of luteinizing hormone-releasing hormone by renal proximal tubular segments in vitro. Stetler-Stevenson MA, et al. **Am J Physiol** 1981 Aug;241(2):F117-22

D-tryptophan-6-LH-RH-at los doses in the treatment of male subfertility. Levalle O, et al. **Andrologia** 1981 May-Jun;13(3):207-11

Luteinizing hormone-releasing hormone analogs with increased anti-ovulatory activity. Erchegyi J, et al. **Biochem Biophys Res Commun** 1981 Jun 16;100(3):915-20

Degradation of luteinizing hormone - releasing hormone and analogs by adenohypophyseal peptidases. Horsthemke B, et al. **Biochem Biophys Res Commun** 1981 May 29;100(2):753-9

Synthesis and degradation of cyclic nucleotides in the pituitary gland, ovary and testis of rats treated with D-Trp6-luteinizing hormone-releasing hormone. Hierowski MT, et al. **Biochim Biophys Acta** 1981 Jul;675(2):232-8

Melatonin effect on the hamster pituitary response to LHRH. Bacon A, et al. **Biol Reprod** 1981 Jun;24(5):993-9

Effect of 20 alpha-dihydroprogesterone, progesterone, and their 5 alpha-reduced metabolites on serum gonadotropin levels and hypothalamic LHRH content. Gilles PA, et al. **Biol Reprod** 1981 Jun; 24(5):1088-97

Direct effects of gonadotropin releasing hormone and its antagonist upon ovarian functions stimulated by FSH, prolactin, ans LH. Jones PB, et al. **Biol Reprod** 1981 May;24(4):747-59

Temporal relationship between the abortifacient effects of GnRH antagonists and hormonal secretion. Rivier C, et al. **Biol Reprod** 1981 Jun;24(5):1061-7

Relative importance of the adenohypophyseal and gonadal sites in inhibitory action of LHRH agonists. Séguin C, et al. **Biol Reprod** 1981 May;24(4):889-901

Site of action of prolactin in the suppression of gonadotropin secretion during lactation in the rat: effect on pituitary responsiveness to LHRH. Smith MS. **Biol Reprod** 1981 Jun;24(5):967-76

Effects of estradiol and progesterone on plasma gonadotropins, prolactin, and LHRH in specific brain areas of ovariectomized rats. Wise PM, et al. **Biol Reprod** 1981 May;24(4):820-30

LHRH systems in brain of platyfish. Münz H, et al. **Brain Res** 1981 Sep 21;221(1):1-13

Effect of manipulating central catecholamines on puberty and the surge of luteinizing hormone and gonadotropin releasing hormone induced by pregnant mare serum gonadotropin in female rats. Sarkar DK, et al. **Brain Res** 1981 Jun 1;213(2):335-49

The fetal development of the luteinizing hormone-releasing hormone (LHRH) neuronal systems of the guinea pig brain. Schwanzel-Fukuda M, et al. **Brain Res Bull** 1981 Sep;7(3):293-315

Ultrastructural immunocytochemical evidence of the presence of a peptide related to ACTH in granules of LHRH nerve terminals in the median eminence of the guinea pig. Beauvillain JC, et al. **Cell Tissue Res** 1981; 218(1):1-6

Immunocytochemistry of luteinizing hormone-releasing hormone, vasopressin, and corticotropin following deafferentation of the basal hypothalamus of the male rat brain. Scott PM, et al. **Cell Tissue Res** 1981;219(2):393-402

The in-vivo effect of Lithospermum ruderale on LHRH activity in the chick. Zeller FJ, et al. **Contraception** 1981 Jul;24(1):77-81

Endocrine and behavioral effects of continuous exposure of male rats to a potent luteinizing hormone-releasing hormone (LHRH) agonist: evidence for central nervous system actions of LHRH. Dorsa DM, et al. **Endocrinology** 1981 Sep;109(3):729-35

Induction and maintenance of gonadotropin and lactogen receptors in hypoprolactinemic rats. Huhtaniemi IT, et al. **Endocrinology** 1981 Aug; 109(2):483-90

Direct inhibitory effect of GnRH on androgen secretion by ovarian interstitial cells. Magoffin DA, et al. **Endocrinology** 1981 Aug; 109(2):661-3

Frequency and amplitude of gonadotropin-releasing hormone stimulation and gonadotropin secretion in the rhesus monkey. Wildt L, et al. **Endocrinology** 1981 Aug;109(2):376-85

Influence of neonatal ovariectomy on the developmental patterns of serum gonadotropins, hypothalamic LH-RH concentration and organ weights in female rats. Döcke F, et al. **Endokrinologie** 1981 Mar; 77(3):273-85

Estrogen effects on LH-RH degrading brain and pituitary enzymes. Bauer K, et al. **Exp Brain Res** 1981;Suppl 3:93-107

The morphology of LRH and oxytocin neurons. Weindl A, et al. **Exp Brain Res** 1981;Suppl 3:1-17 (37 ref.)

Photo-affinity inactivation of gonadotropin releasing hormone receptors. Hazum E. **FEBS Lett** 1981 Jun 1;128(1):111-3

Slow cholinergic and peptidergic transmission in sympathetic ganglia. Brown DA, et al. **Fed Proc** 1981 Sep;40(11):2625-30

Role of an LHRH-like peptide as a neurotransmitter is sympathetic ganglia of the frog. Jan LY, et al. **Fed Proc** 1981 Sep;40(11):2560-4

Pituitary response to luteinizing hormone-releasing hormone during haloperidol-induced hyperprolactinemia. Del Carmen Díaz M, et al. **Fertil Steril** 1981 Jun;35(6):626-8

Failure to interrupt established pregnancy in humans by D-tryptophan-6-luteinizing hormone-releasing hormone. Tolis G, et al. **Fertil Steril** 1981 Aug;36(2):241-2

Effect of LH-RH treatment on hypothalamo-pituitary-gonadal axis and Leydig cell ultrastructure in cryptorchid boys. Hadziselimovic F, et al. **Horm Res** 1980;13(6):358-66

The fate of conceptuses in rats receiving an intrauterine injection of luteinizing hormone-releasing hormone (LRH) prior to implantation. Jones RC. **Int J Fertil** 1981;26(2):120-3

Suppression of androgen production by D-tryptophan-6-luteinizing hormone-releasing hormone in man. Tolis G, et al. **J Clin Invest** 1981 Sep;68(3):819-22

Effects of oestradiol, hypothalamic extracts and luteinizing hormone releasing hormone on rat anterior pituitary gland gonadotrophin release in vitro before and after the preovulatory luteinizing hormone surge at pro-oestrus. Elias KA, et al. **J Endocrinol** 1981 Sep;90(3):345-54

Repetitive treatment with gonadotrophin releasing factor or a long-acting analogue upon gonadotrophin secretion in the ferret. Gledhill B, et al. **J Endocrinol** 1981 Aug;90(2):275-83

Time-related secretion of gonadotrophins after a single injection of steroid-free bovine follicular fluid in prepubertal and adult female rats. Hermans WP, et al. **J Endocrinol** 1981 Jul;90(1):69-76

Immunocytochemical localization of luteinizing hormone-releasing hormone (LHRH) in Vibratome-sectioned brain. Joseph SA, et al. **J Histochem Cytochem** 1981 Feb;29(2):247-54

Immunocytochemical analysis of the rat pineal gland using antisera generated against luteinizing hormone-releasing hormone (LHRH). Piekut DT, et al. **J Histochem Cytochem** 1981 May;29(5):616-22

An approach to the elucidation of metabolic breakdown products of the luteinizing hormone-releasing hormone. Stetler-Stevenson MA, et al. **J Med Chem** 1981 Jun;24(6):688-92

Inadequate corpus luteum function after the induction of ovulation in anoestrous ewes by LH-RH or an LH-RH agonist. McNeilly AS, et al. **J Reprod Fertil** 1981 Sep;63(1):137-44

Stimulation of pituitary and testicular functions with LH-RH agonist or pulsatile LH-RH treatment in the rhesus monkey during the non-breeding season. Wickings EJ, et al. **J Reprod Fertil** 1981 Sep; 63(1):129-36

Development of a quotidian increase in pituitary responsiveness to GnRH in prepubertal female rats. Wilkinson M, et al. **J Reprod Fertil** 1981 Jul;62(2):393-8

Prolactin and LH release in response to LH-RH and TRH in ewes during dioestrus, pregnancy and post partum. Wright PJ, et al. **J Reprod Fertil** 1981 Jul;62(2):447-53

Control of gonadotrophic hormone release in trout: influence of synthetic LH-RH and LH-RH analogues in vivo and in vitro. Crim LW, et al. **Life Sci** 1981 Jan 12;28(2):129-35

Binding of luteinizing hormone-releasing hormone analogues to dispersed rat pituitary cells. Meidan R, et al. **Life Sci** 1981 Apr 27; 28(17):1961-7

Modulation of FSH-controlled steroidogenesis in rat granulosa cells: direct in-vitro effects of LHRH and ICI-118630. Hillier SG, et al. **Mol Cell Endocrinol** 1981 Aug;23(2):193-205

Reversible inhibition of testicular steroidogenesis and spermatogenesis by a potent gonadotropin-releasing hormone agonist in normal men: an approach toward the development of a male contraceptive. Linde R, et al. **N Engl J Med** 1981 Sep 17;305(12):663-7

Gonadotropin releasing hormone stimulates calmodulin redistribution in rat pituitary. Conn PM, et al. **Nature** 1981 Jul 16;292(5820):264-5

Age-related changes in dopamine, LHRH and somatostatin in the rat hypothalamus. Hoffman GE, et al. **Neurobiol Aging** 1980 Summer; 1(1):27-37

Inhibin-like activity in extracts of rabbit placentae. Hochberg Z, et al. **Placenta** 1981 Jul-Sep;2(3):259-64

Hormonal regulation of cytodifferentiation and intercellular communication in cultured granulosa cells. Amsterdam A, et al. **Proc Natl Acad Sci USA** 1981 May;78(5):3000-4

Increased pituitary sensitivity to luteinizing hormone releasing hormone at puberty: an event of proestrus. Johnson JH, et al. **Proc Soc Exp Biol Med** 1981 Jul;167(3):434-7

Continuous infusion of luteinizing hormone releasing hormone (LHRH) in patients with anorexia nervosa. Beumont PJ, et al. **Psychol Med** 1981 Aug;11(3):477-84

Facilitation of mounting behavior in male rats by intracranial injections of luteinizing hormone-releasing hormone. Dorsa DM, et al. **Regul Pept** 1980 Oct;1(2):147-55

Degradation of luteinizing hormone-releasing hormone by serum and plasma in vitro. McDermott JR, et al. **Regul Pept** 1981 May; 2(2):69-79

Vasoactive intestinal peptide stimulates luteinizing hormone-releasing hormone release from median eminence synaptosomes. Samson WK, et al. **Regul Pept** 1981 Aug;2(4):253-64

Studies on mechanism of action of luteinizing releasing hormone (LH-RH) in ovulation of fish—intracellular distribution of LH-RH-A in pituitary gonadotrophs as revealed by electron-microscopic autoradiography. Pan XG, et al. **Sci Sin** 1981 Jul;24(7):982-8

Immunohistochemical demonstration of a testicular substance related to luteinizing hormone-releasing hormone. Paull WK, et al. **Science** 1981 Sep 11;213(4513):1263-4

[Regulation of the endocrine function of the placenta] Presl J. **Cesk Gynekol** 1981 Jul;46(6):466-7 **(Cze)**

[Intermittent liberation of gonadoliberin (GnRH) by the rat hypothalamus in vitro] Bourguignon JP, et al. **C R Trav Lab Carlsberg** 1981; 175(3):389-96 (Eng. Abstr.) **(Fre)**

[Gonadocrinin-like activity of the peritoneal fluid during the menstrual cycle in the normal female] Demoulin A, et al. **C R Trav Lab Carlsberg** 1981;175(3):377-84 (Eng. Abstr.) **(Fre)**

[Intracellular mechanism for the action of inhibin on the secretion of the follicular-stimulating hormone and luteinizing hormone induced by LH-RH in vitro] Lecomte-Yerna MJ, et al. **C R Trav Lab Carlsberg** 1981;175(3):385-8 (Eng. Abstr.) **(Fre)**

[Changes of hypothalamic LH-RH content induced by estradiol injection into female rats (author's transl)] Saito A. **Nippon Sanka Fujinka Gakkai Zasshi** 1981 Aug;33(8):1227-34 (Eng. Abstr.) **(Jpn)**

[Indirect effects of synthetic LHRH on cervical mucus characteristics] Meden-Vrtovec H. **Jugosl Ginekol Opstet** 1980 May-Aug; 20(3-4):236-42 (Eng. Abstr.) **(Scr)**

LIPOTROPIN

beta-Adrenergic stimulation of the release of ACTH- and LPH-related peptides from the pars intermedia of the rat pituitary gland. Tilders FJ, et al. **Acta Endocrinol (Copenh)** 1981;97(3):343-51

Conformational properties of central nervous system myelin basic protein, beta-endorphin, and beta-lipotropin in water and in the presence of anionic lipids. Mattice WL, et al. **Biopolymers** 1981 Jul; 20(7):1421-34

beta-lipotrophin and beta-endorphin plasma levels during pregnancy. Genazzani AR, et al. **Clin Endocrinol (Oxf)** 1981 Apr;14(4):409-18

Effects of beta-lipotropin and beta-lipotropin-derived peptides on aldosterone production in the rat adrenal gland. Matsuoka H, et al. **J Clin Invest** 1981 Sep;68(3):752-9

Parallel stimulation of ACTH, beta-LPH + beta-endorphin and alpha-MSH release by alpha-adrenergic agents in rat anterior pituitary cells in culture. Raymond V, et al. **Mol Cell Endocrinol** 1981 Jun; 22(3):295-303

Physical conditioning facilitates the exercise-induced secretion of beta-endorphin and beta-lipotropin in women. Carr DB, et al. **N Engl J Med** 1981 Sep 3;305(10):560-3

Vasopressin stimulates release of beta-lipotropin and beta-endorphin in conscious rats as measured by radioimmunoassay of unextracted plasma. Anhut H, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb; 316(1):59-63

The influence of fragments of the LPH chains on learning, memory and attention in animals and man. Sandman CA, et al. **Pharmacol Ther [B]** 1981;13(1):39-60 (76 ref.)

LITHIUM

Mechanism for exoelectron emission mainly from LiF. Samuelsson LI. **Acta Radiol [Suppl] (Stockh)** 1979;359:1-93

Thermoluminescence dosimetry in the muGy range. Theoretical and experimental investigations of the optimum performance of a LiF-TLD system. Spanne P. **Acta Radiol [Suppl] (Stockh)** 1979;360:1-118

Lithium capsule. Holland PJ. **Am Fam Physician** 1981 Sep;24(3):147-8

Physostigmine and lithium response in the schizophrenias. Edelstein P, et al. **Am J Psychiatry** 1981 Aug;138(8):1078-81

Inaccurate creatinine clearance tests [letter] Pulier M. **Am J Psychiatry** 1981 Sep;138(9):1258-9

Determination of lithium in small-animal tissues at physiological levels by flame emission photometry. Pickett EE, et al. **Anal Biochem** 1981 Apr;112(2):213-8

Prophylactic lithium carbonate with and without imipramine for bipolar 1 patients. A double-blind study. Quitkin FM, et al. **Arch Gen Psychiatry** 1981 Aug;38(8):902-7

Regulation of lithium in cerebrospinal fluid of the cat by the choroid plexus isolated in situ. Yen MH, et al. **Arch Int Pharmacodyn Ther** 1981 Jun;251(2):217-27

Toxicity and renal elimination of lithium in rats of different ages. Kersten L. **Arch Toxicol** 1981 Apr;47(2):135-44

Olfactory discrimination of lithium chloride by the coyote (Canis latrans). Ellins SR, et al. **Behav Neural Biol** 1981 Feb;31(2):214-24

Failure of albino guinea pigs to exhibit Lavin's poisoned partner effect. Revusky S, et al. **Behav Neural Biol** 1981 May;32(1):111-3

Current perspectives in lithium prophylaxis. International symposium, Vienna, October 19-20, 1979. **Bibl Psychiatr** 1981;(161):1-248 (Eng, Mul)

Practical guide-lines of lithium prophylaxis. Kerry RJ. **Bibl Psychiatr** 1981;(161):197-205

Lithium carbonate in the treatment of acute depressive illness. Khan MC. **Bibl Psychiatr** 1981;(161):244-8

Responders and non-responders to lithium therapy. Some potential biological indicators. Mendlewicz J. **Bibl Psychiatr** 1981;(161):63-8 (39 ref.)

Prophylactic and therapeutic profile of lithium. Peselow E, et al. **Bibl Psychiatr** 1981;(161):1-31 (158 ref.)

Kidney morphology and function in lithium-treated patients. Vestergaard P, et al. **Bibl Psychiatr** 1981;(161):104-14 (17 ref.)

Memory performances in depressed patients during prophylactic treatment with lithium salts. Zerbi F, et al. **Bibl Psychiatr** 1981;(161):190-6

The hamster adipocyte adenylate cyclase system. II. Regulation of enzyme stimulation and inhibition by monovalent cations. Aktories K, et al. **Biochim Biophys Acta** 1981 Aug 5;676(1):59-67

Binding constants of Li+, K+, and Tl+ in the gramicidin channel determined from water permeability measurements. Dani JA, et al. **Biophys J** 1981 Aug;35(2):485-99

Lithium intoxication treated by peritoneal dialysis. Brown EA, et al. **Br J Clin Pract** 1981 Feb;35(2):90-1

Lithium induces rapid relief of depression in tricyclic antidepressant drug non-responders. Dé Montigny C, et al. **Br J Psychiatry** 1981 Mar; 138:252-6

Increase in mesolimbic electrical self-stimulation after chronic haloperidol: reversal by L-DOPA or lithium. Seeger TF, et al. **Brain Res** 1981 Jun 29;215(1-2):404-9

Does lithium prevent neutropenia caused by antidepressants? [letter] Vasconcelos JA, et al. **Can Med Assoc J** 1981 Jul 1;125(1):20

Nephrotic syndrome associated with lithium therapy. Alexander F, et al. **Clin Nephrol** 1981 May;15(5):267-71

Effects of diclofenac on lithium kinetics. Reimann IW, et al. **Clin Pharmacol Ther** 1981 Sep;30(3):348-52

Severe lithium poisoning. Marshall SM, et al. **Drug Intell Clin Pharm** 1981 Jul-Aug;15(7-8):598-9

Effect of chronic lithium treatment on isolation-induced behavioral and biochemical effects in mice. Frances H, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):337-41

Phototransfer, sensitization and re-estimation of dose in lithium fluoride TLD. Jain VK. **Health Phys** 1981 Aug;41(2):363-70

Lithium excretion and therapeutic response in mania. Sampath G, et al. **Indian J Med Res** 1981 May;73:768-71

Kidney function in patients with affective disorders with and without lithium therapy. Wahlin A, et al. **Int Pharmacopsychiatry** 1980; 15(4):253-9

Lithium prophylaxis and the kidney. Bakris GL, et al. **J Affective Disord** 1981 Mar;3(1):37-42

Bipolar affective disorder, lithium carbonate and Ca++ ATPase. Choi SJ, et al. **J Affective Disord** 1981 Jun;3(2):77-9

A longitudinal record study of renal function in patients treated with lithium. Hwu HG, et al. **J Affective Disord** 1981 Jun;3(2):101-9

The activity of the lithium--sodium countertransport system in erythrocytes in depression and mania. Rybakowski J, et al. **J Affective Disord** 1981 Mar;3(1):59-64

Antinuclear antibodies and histocompatibility antigens in patients on long-term lithium therapy. Whalley LJ, et al. **J Affective Disord** 1981 Jun;3(2):123-30

Effects of fluoride, lithium and strontium on extracellular polysaccharide production by Streptococcus mutans and Actinomyces viscosus. Treasure P. **J Dent Res** 1981 Aug;60 Spec No C:1601-10

Dependence of water movement on sodium transport in kidney proximal tubule: a microperfusion study substituting lithium for sodium. Corman B, et al. **J Membr Biol** 1981;62(1-2):105-11

Action of lithium on the adrenergic nerve ending. Beaty O 3d, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):309-17

Interaction of lithium and disulfiram in hexobarbital hypnosis: possible role of the 5-HT system. Minegishi A, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):481-7

The effect of lithium on electrolyte transport by the in situ choroid plexus of the cat. Reed DJ, et al. **J Physiol (Lond)** 1980 Dec;309:329-39

Determination of lithium-induced impairment of distal water reabsorption. Thomsen K, et al. **J Psychiatr Res** 1981;16(2):79-85

Lithium carbonate for recurrent fever and neutropenia. Gerner RH, et al. **JAMA** 1981 Oct 2;246(14):1584-6

Renal toxicity of lithium and its implications. DePaulo JR Jr, et al. **Johns Hopkins Med J** 1981 Jul;149(1):15-21

Further studies on the potentiating effect of lithium chloride on methamphetamine-induced stereotypy in mice. Miyauchi T, et al. **Jpn J Pharmacol** 1981 Feb;31(1):61-8

Chromosome studies of patients on long-term lithium therapy for psychiatric disorders. Garson OM, et al. **Med J Aust** 1981 Jul 11; 2(1):37-9

Case 17-1981: chronic interstitial nephritis from lithium therapy [letter] Wahlin A, et al. **N Engl J Med** 1981 Aug 13;305(7):408

Post-amphetamine depression of self-stimulation behavior in rats: prophylactic effects of lithium. Predy PA, et al. **Neurosci Lett** 1981 May 29;23(3):343-7

Leukocytosis during long-term lithium treatment. Yassa R. **NY State J Med** 1981 Sep;81(10):1479-80

John F.J. Cade, 1912 to 1980: a reminiscence. Johnson FN. **Pharmacopsychiatria** 1981 Jul;14(4):148-9

Thermal quenching by phototransfer in LiF TLD-100. Kathuria SP, et al. **Phys Med Biol** 1981 Jul;26(4):707-10

Effect of lithium intake on sodium and lithium appetite in sodium deficient cattle. Sly J, et al. **Physiol Behav** 1981 Jul;27(1):147-52

Lithium promotes entrainment of rats to long circadian light-dark cycles. McEachron DL, et al. **Psychiatry Res** 1981 Aug;5(1):1-9

Acute amphetamine response predicts antidepressant and antipsychotic responses to lithium carbonate in schizophrenic patients. van Kammen DP, et al. **Psychiatry Res** 1981 Jun;4(3):313-25

Continuation therapy with lithium and amitriptyline in unipolar depressive illness: a controlled clinical trial. A report by the Medical Research Council Drug Trials Subcommittee. **Psychol Med** 1981 May; 11(2):409-16

Lithium increases serotonin release and decreases serotonin receptors in the hippocampus. Treiser SL, et al. **Science** 1981 Sep 25; 213(4515):1529-31

Lithium inhibits adenylate cyclase of human platelets. Imandt L, et al. **Thromb Haemost** 1981 Apr 30;45(2):142-5

Use of stimulant medication in treating pervasive developmental disorder [letter] Sporn A, et al. **Am J Psychiatry** 1981 Jul;138(7):997

Pharmacokinetics and behavioral effects of methylphenidate in Thoroughbred horses. Shults T, et al. **Am J Vet Res** 1981 May; 42(5):722-6

Methylphenidate impairs learning and memory in normal adults. Wetzel CD, et al. **Behav Neural Biol** 1981 Apr;31(4):413-24

Liquid-chromatographic analysis for methylphenidate (Ritalin) in serum. Soldin SJ, et al. **Clin Chem** 1979 Mar;25(3):401-4

Behavioral and neurochemical interactions of dextroamphetamine and methylphenidate in rats. Reigle TG, et al. **J Pharm Sci** 1981 Jul; 70(7):816-8

Optimal dosages of methylphenidate for improving the learning and behavior of hyperactive children. Charles L, et al. **JDBP** 1981 Sep; 2(3):78-81

Intracerebral des-tyrosine-gamma-endorphin inhibits methylphenidate induced locomotor activity. Davis KL, et al. **Life Sci** 1981 May 21; 28(21):2421-4

Antagonism of methylphenidate-induced behavior by neostigmine or hemicholinium-3. Ward HE Jr, et al. **Neuropharmacology** 1981 Jul; 20(7):705-9

Self-stimulation and amphetamine: tolerance to d and l isomers and cross tolerance to cocaine and methylphenidate. Leith NJ, et al. **Psychopharmacology (Berlin)** 1981;74(1):23-8

METHYSERGIDE

Reactivity of isolated trachea, bronchus and lung strip of cats of carbachol, 5-hydroxytryptamine and histamine: evidence for the existence of methysergide-sensitive receptors. Chand N. **Br J Pharmacol** 1981 Aug; 73(4):853-7

Effects of methysergide or phenoxybenzamine on the renal and cardiovascular responses to endotoxin in rats. Keeler R. **Circ Shock** 1981;8(3):361-8

A pre-junctional action of 5-hydroxytryptamine and methysergide on noradrenergic nerves in dog isolated saphenous vein. Watts AD, et al. **J Pharm Pharmacol** 1981 Aug;33(8):515-20

Effect of lergotrile mesylate and methysergide on morphine induced increase in prolactin release. Ratner A, et al.

Proc West Pharmacol Soc 1981;24:335-9

MOTIVATION

The temporal structure of motivation IV: A reexamination of extinction effects in intracranial reward. Katz RJ. **Behav Neural Biol** 1981 Jun; 32(2):191-200

Effect of injury to the serotoninergic and noradrenergic brain systems on food and defensive conditioned reflexes in rats. Gromova EA, et al. **Neurosci Behav Physiol** 1981 Jan-Feb;11(1):10-5

MOTOR ACTIVITY

Kainic acid induced lesion of ventral tegmental area: locomotor effect of apomorphine. Morgenstern R. **Acta Biol Med Ger** 1980; 39(8-9):911-5

The influence of microinjections of cholinomimetics into hypothalamus on the locomotor activity of rats. Plech A. **Agressologie** 1979; 20(D):279-82

Effect of haloperidol withdrawal on motor activity and circadian rhythm of rats. Kumar A, et al. **Arzneimittelforsch** 1981;31(7):1096-8

Effects of 60-Hz electric fields on avoidance behavior and activity of rats. Hjeresen DL, et al. **Bioelectromagnetics** 1980;1(3):299-312

Effect of short electromagnetic pulses on brain acetylcholine content and spontaneous motor activity of mice. Modak AT, et al. **Bioelectromagnetics** 1981;2(1):89-92

Differential effects of estrogen and androgen on locomotor activity induced in castrated male rats by amphetamine, a novel environment, or apomorphine. Menniti FS, et al. **Brain Res** 1981 Jul 6; 216(1):89-107

Role of dorsal mesencephalic reticular formation and deep layers of superior colliculus in turning behaviour elicited from the striatum. Morelli M, et al. **Brain Res** 1981 Jun 29;215(1-2):337-41

Disproportionate increases in locomotor activity in response to hormonal and photic stimuli following regional neurochemical depletions of serotonin. Waldbillig RJ, et al. **Brain Res** 1981 Jul 27;217(1):79-91

Behavioural effects of cathinone, an amine obtained from Catha edulis Forsk.: comparisons with amphetamine, norpseudoephedrine, apomorphine and nomifensine. Zelger JL, et al. **Bull Narc** 1980; 32(3):67-81

Supersensitivity of nigral serotonin receptors and rat rotational behaviour. Blackburn TP, et al. **Eur J Pharmacol** 1981 May 8;71(2-3):343-6

Pharmacological studies with several analogs of mazindol: correlation between effects on dopamine uptake and various in vivo responses. Heikkila RE, et al. **Eur J Pharmacol** 1981 May 8;71(2-3):277-86

Effect of L-histidine and chlorcyclizine on apomorphine-induced climbing behaviour and methamphetamine stereotypy in mice. Joshi VV, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):499-502

Involvement of dopamine in circling responses to muscimol depends on intranigral site of injection. Kilpatrick IC, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):407-19

Potentiation by Des-Tyr-gamma-endorphin on apomorphine-induced changes in rat open field behavior. Nickolson VJ. **Eur J Pharmacol** 1981 Jun 10;72(1):77-81

Detailed analysis of the effects of apomorphine and d-amphetamine on spontaneous locomotor behaviour of rats as measured in a TV-based, automated open-field system. Nickolson VJ. **Eur J Pharmacol** 1981 Jun 10;72(1):45-56

Involvement of noradrenergic and dopaminergic neurons in shock-induced jumping in rats. Nishikawa T, et al. **Eur J Pharmacol** 1981 May 22;71(4):429-36

Injection of low doses of apomorphine into the nucleus accumbens of rats reduces locomotor activity. Van Ree JM, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):107-11

Effects of microinjection of 2-chloro-11 (2-dimethylaminoethoxy)-dibenzo[b,f]-thiepine (zotepine), thioridazine and haloperidol into the striatum and nucleus accumbens on stereotypic behaviour and motor activity. Lai H, et al. **J Pharm Pharmacol** 1981 Apr;33(4):252-4

Age-related changes in the central catecholaminergic function and its interaction with methamphetamine during postnatal life in the rat. Nomura Y, et al. **J Pharm Pharmacol** 1981 Apr;33(4):264-6

Backward walking induced by L-5-hydroxytryptophan in mice. Shimomura K, et al. **Jpn J Pharmacol** 1981 Feb;31(1):39-46

Induction of behavioral supersensitivity to apomorphine by DFP treatment. Davis KL, et al. **Life Sci** 1981 Apr 27;28(17):1953-9

Intracerebral des-tyrosine-gamma-endorphin inhibits methylphenidate induced locomotor activity. Davis KL, et al. **Life Sci** 1981 May 21; 28(21):2421-4

Differential effects of several dopamine uptake inhibitors and releasing agents on locomotor activity in normal and in reserpinized mice. Heikkila RE. **Life Sci** 1981 Apr 27;28(17):1867-73

Dopamine independent rotational response to unilateral intranigral injection of serotonin. Oberlander C, et al. **Life Sci** 1981 Jun 8; 28(23):2595-601

Single or repeated administration of small doses of apomorphine on water intake and activity in water-deprived rats. Dourish CT, et al. **Neuropharmacology** 1981 Mar;20(3):257-60

Multi-dimensional analyses of behavior in mice treated with alpha-endorphin. Kameyama T, et al. **Neuropharmacology** 1981 Mar; 20(3):247-50

Brain levels of noradrenalin, dopamine, and serotonin in rats with different levels of motor activity. Semenova TP, et al. **Neurosci Behav Physiol** 1981 Mar-Apr;11(2):153-5

Locomotor activity, defecation score and corticosterone levels during an openfield · exposure: a comparison among individually and group-housed rats, and genetically selected rat lines. Gentsch C, et al. **Physiol Behav** 1981 Jul;27(1):183-6

The locomotor and exploratory activities in rats after lesion of hippocampal pyramidal cells with kainic acid. Kleinrok Z, et al. **Pol J Pharmacol Pharm** 1980;32(5):625-37

Effects of a piperazine derivative piribedil, on exploration; locomotor activity and social behaviour in the rat. File SE. **Prog Neuropsychopharmacol** 1981;5(3):245-55

Neuroanatomical dissociation of thyrotropin-releasing hormone induced shaking behavior and thermogenic mechanisms. Kalivas PW, et al. **Regul Pept** 1981 Feb;1(5):335-45

[Central depletion of transmitters by reserpine and motor behavior in the rat (author's transl)] Funk KF, et al. **Acta Biol Med Ger** 1980; 39(8-9):923-7 (Eng. Abstr.) (Ger)

[Mechanism of pantogam potentiation of certain effects of hexobarbital and sodium barbital and inhibition of phenamine hyperactivity] Avakumov VM, et al. **Farmakol Toksikol** 1981 Jan-Feb;44(1):30-4 (Eng. Abstr.) (Rus)

MOTOR SKILLS

Diazepam and driving ability. Landauer AA. **Med J Aust** 1981 Jun 13; 1(12):624-6

The effects of amoxapine and ethanol on psychomotor skills related to driving: a placebo and standard controlled study. Wilson WH, et al. **Prog Neuropsychopharmacol** 1981;5(3):263-70

[Motor reactivity during lithium prophylaxis] Opgenoorth E, et al. **Bibl Psychiatr** 1981;(161):152-69 (Eng. Abstr.) (Ger)

[Influence of thioridazine on cognitive, psychomotor, and reaction performance in patients with dysthymic-depressive syndrome (author's transl)] Meyer FP, et al. **Pharmacopsychiatria** 1981 May;14(3):94-9 (Ger)

MSH

Processing, turnover and release of corticotropins, endorphins and melanotropin in the toad pituitary intermediate lobe. Loh YP. **Ciba Found Symp** 1981;(81):55-78

Functions of alpha-melanotropin and other opiomelanocortin peptides in labour, intrauterine growth and brain development. Swaab DF, et al. **Ciba Found Symp** 1981;(81):196-217

Endogenous alpha-melanotropin and central dopamine systems in physical and psychological stress. Monnet F, et al. **Exp Brain Res** 1981; 42(2):203-11

Parallel stimulation of ACTH, beta-LPH + beta-endorphin and alpha-MSH release by alpha-adrenergic agents in rat anterior pituitary cells in culture. Raymond V, et al. **Mol Cell Endocrinol** 1981 Jun; 22(3):295-303

alpha-MSH, MIF-I and melatonin: effects on novelty-induced defecation, plasma 11-OHCS and central catecholamines in rats. Datta PC, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:143-54

Effects of alpha-MSH and beta-endorphin on startle reflex in rat. Hoehler FK, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:137-41

Stimulatory effect of prostaglandin E1 on thyroliberin-induced alpha-melanotropin release from perifused neuro-intermediate lobes of frog pituitary gland. Leroux P, et al. **Prostaglandins** 1981 Apr; 21(4):599-608

NEUROREGULATORS

The insect neuropeptide proctolin can affect the CNS and the smooth=muscle of mammals. Schulz H, et al. **Acta Biol Med Ger** 1981; 40(2):K1-5

Neurotransmitters in the cochlea and the cochlear nucleus. Klinke R. **Acta Otolaryngol (Stockh)** 1981 May-Jun;91(5-6):541-54 (88 ref.)

Effect of electroconvulsive treatment on brain monoamine content, pituitary-adrenal function and plasma prolactin. Arató M, et al. **Acta Physiol Acad Sci Hung** 1980;56(2):163-71

Amino acid neurotransmitters. **Adv Biochem Psychopharmacol** 1981; 29:1-572

Neuron-glia interactions in the biosynthesis and release of transmitter amino acids. Hamberger A, et al. **Adv Biochem Psychopharmacol** 1981; 29:509-18 (29 ref.)

Glutamate as a transmitter of the hippocampal commissural system. Nitsch C. **Adv Biochem Psychopharmacol** 1981;29:97-104

Pharmacology of excitatory amino acid transmitters. Watkins JC. **Adv Biochem Psychopharmacol** 1981;29:205-12 (31 ref.)

Evidence for a dual role of GABA as a synaptic transmitter and a promoter of synaptogenesis. Wolff JR. **Adv Biochem Psychopharmacol** 1981;29:459–65 (29 ref.)

General characteristics, localization, and adaptative responsiveness of neurotransmitter–sensitive adenylate cyclases in the central nervous system. Bockaert J. **Adv Cyclic Nucleotide Res** 1981;14:611–28

Inhibition of adenylate cyclase by hormones and neurotransmitters. Jakobs KH, et al. **Adv Cyclic Nucleotide Res** 1981;14:173–87

Transport models of the neurotransmitter–receptor interaction. Vieth WR, et al. **Ann NY Acad Sci** 1981;369:99–111

Dual action of meperidine on the frog neuromuscular junction: a prejunctional, opiate receptor–mediated depression of transmitter release and a postjunctional, nonopiate receptor effect on the endplate. Durham HD, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):150–65

Changes in brain biogenic amines in cats performing a symmetrically reinforced go–nogo visual discrimination task. Kitsikis A, et al. **Behav Neural Biol** 1981 Jun;32(2):133–47

Divalent cations and transmitter release at low concentration of tetrodotoxin. Dascal N, et al. **Biophys J** 1981 Sep;35(3):573–86

Tests of an electrostatic screening hypothesis of the inhibition of neurotransmitter release by cations at the frog neuromuscular junction. Misler S, et al. **Biophys J** 1980 Jul;31(1):9–30

Diet, neurotransmitters and brain function. Anderson GH. **Br Med Bull** 1981 Jan;37(1):95–100 (69 ref.)

The neuropeptide proctolin acts directly on Limulus cardiac muscle to increase the amplitude of contraction. Benson JA, et al. **Brain Res** 1981 Jun 1;213(2):449–54

Evidence for glutamate as the neurotransmitter of corticothalamic and corticorubral pathways. Bromberg MB, et al. **Brain Res** 1981 Jun 29; 215(1–2):369–74

Patterns of endogenous amino acid release from slices of rat and guinea–pig olfactory cortex. Collins GG, et al. **Brain Res** 1981 Jan 5; 204(1):103–20

Fourth ventricular tanycytes: a possible relationship with monoaminergic nuclei. Felten DL, et al. **Brain Res Bull** 1981 May;6(5):427–36

Immunocytochemical identification of proctolinlike immunoreactivity in the terminal ganglion and hindgut of the cockroach Periplaneta americana (L.). Eckert M, et al. **Cell Tissue Res** 1981;217(3):633–45

Diamide, temperature and spontaneous transmitter release at the neuromuscular junction: stimulation of exocytosis by a direct effect on membrane fusion? Pubiicover SJ, et al. **Eur J Pharmacol** 1981 Mar 12; 70(2):203–11

Electrical responses of pineal cells to melatonin and putative transmitters. Evidence for circadian changes in sensitivity. Semm P, et al. **Exp Brain Res** 1981;43(3–4):361–70

Role of neurotransmitter release and cyclic AMP–dependent membrane phosphorylation in low voltage myocardial automaticity. Saxon ME, et al. **Experientia** 1981 Jul 15;37(7):731–4

Biophysical aspects of transmitter action. Adams PR. **Fed Proc** 1981 Sep; 40(11):2611–3

Neuroendocrine involvement in regulation of isocitrate & glucose–6–phosphate dehydrogenase activities in the fresh water field crab Oziotelphusa senex senex. Purushotham KR, et al. **Indian J Exp Biol** 1981 Apr;19(4):399–400

Neurotransmitter receptors: neuroanatomical localization through autoradiography. Murrin LC. **Int Rev Neurobiol** 1981;22:111–71 (379 ref.)

Mechanisms of synaptic modulation. Shain W, et al. **Int Rev Neurobiol** 1981;22:205–50 (254 ref.)

On the structural and phyletic origin of the aminergic nerves of the hypophysis of frog tadpoles (Rana temporaria) with special reference to pars distalis. Aronsson S, et al. **J Comp Neurol** 1981 Aug 10; 200(3):315–21

Respiratory depression by GABA–ergic drugs in the preterm rabbit. Hedner J, et al. **J Dev Physiol** 1980 Dec;2(6):401–7

Cyclic AMP, 5–HT, and the modulation of transmitter release at the crayfish neuromuscular junction. Enyeart J. **J Neurobiol** 1981 Sep; 12(5):505–13

The effect of anti–synaptosomal membrane antibodies of neurotransmitter uptake. Hofstein R, et al. **J Neurochem** 1981 Jul;37(1):14–21

Aspartate and glutamate as possible neurotransmitters in the visual cortex. Baughman RW, et al. **J Neurosci** 1981 Apr;1(4):427–39

Transmitter release properties along regenerated nerve processes at the frog neuromuscular junction. Decino P. **J Neurosci** 1981 Mar; 1(3):308–17

Synaptic transmission within the central nervous system. Neatherlin JS, et al. **J Neurosurg Nurs** 1981 Jun;13(3):146–9

A smooth muscle inhibitory material from the bovine retractor penis and rat anococcygeus muscles. Gillespie JS, et al. **J Physiol (Lond)** 1980 Dec;309:55–64

Transmitter control of voltage–dependent currents. Pellmer TC. **Life Sci** 1981 May 18;28(20):2199–205 (36 ref.)

The status of glycine as a supraspinal neurotransmitter. Pycock CJ, et al. **Life Sci** 1981 Jun 15;28(24):2679–86 (81 ref.)

An opiate system in the goldfish retina. Djamgoz MB, et al. **Nature** 1981 Aug 13;292(5824):620–3

Tetanus toxin and botulinum A toxin inhibit release and uptake of various transmitters, as studied with particulate preparations from rat brain and spinal cord. Bigalke H, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jun;316(3):244–51

Age and neurochemical correlates of radial maze performance in rats. Ingram DK, et al. **Neurobiol Aging** 1981 Spring;2(1):41–7

Age–related alterations in neurotransmitter receptors: an electrophysiological and biochemical analysis. Lippa AS, et al. **Neurobiol Aging** 1981 Spring;2(1):3–8

Recovery cycles of visual cortical primary responses during pharmacological and electrical intervention on monoaminergic systems of the rat brain. Vorob'ev VV, et al. **Neurosci Behav Physiol** 1981 Mar–Apr;11(2):129–33

Peptides as neurotransmitters: focus on the enkephalins and endorphins. Miller RJ. **Pharmacol Ther [B]** 1981;12(1):73–108 (214 ref.)

Sleep deprivation: effects on circadian rhythms of rat brain neurotransmitter receptors. Wirz–Justice A, et al. **Psychiatry Res** 1981 Aug;5(1):67–76

Effect of chronic methylmercury exposure on activities of neurotransmitter enzymes in rat cerebellum. Tsuzuki Y. **Toxicol Appl Pharmacol** 1981 Sep 15;60(2):379–81

[Diet, neurotransmitters and brain function (editorial)] **S Afr Med J** 1981 Aug 8;60(6):221 **(Afr)**

[Clinical implications of present knowledge respecting neuropharmacologic control of antipituitary hormones] Martin–Du Pan R, et al. **Schweiz Med Wochenschr** 1980 Nov 29;110(48):1784–1814 (346 ref.) (Eng. Abstr.) **(Fre)**

[Hypophyseal hormones––neurotransmitters? (editorial)] Korczyn A. **Harefuah** 1980 Dec 15;99(12):441–2 **(Heb)**

[Role of dopamine receptors in regulating glutamatergic synaptic transmission in the rat neostriatum] Godukhin OV, et al. **Fiziol Zh SSSR** 1981 Mar;67(3):384–9 (Eng. Abstr.) **(Rus)**

[Neurohumoral regulation of the microcirculation in vibration–related disorders] Kostiuk IF, et al. **Vrach Delo** 1981;(6):100–2 **(Rus)**

[Mechanisms of the central action of lithium] Sinitskil VN, et al. **Zh Nevropatol Psikhiatr** 1981;81(4):567–75 (Eng. Abstr.) **(Rus)**

NEUROTENSIN

The regional distribution of somatostatin, substance P and neurotensin in human brain. Cooper PE, et al. **Brain Res** 1981 Aug 10; 218(1–2):219–32

Immunocytochemical localization of neurotensin–containing neurons in the hypothalamus of the Japanese quail, Coturnix coturnix japonica. Yamada S, et al. **Cell Tissue Res** 1981;218(1):29–39

Neurotensin–like immunoreactivity in the nervous system of hydra. Grimmelikhuijzen CJ, et al. **Histochemistry** 1981;72(2):199–209

Neurotensin–induced contractions in venous smooth muscle. Helle KB, et al. **J Auton Nerv Syst** 1980 Jul;2(2):143–55

Synthesis of peptides by the solid–phase method. 6. Neurotensin, fragments, and analogues. St–Pierre S, et al. **J Med Chem** 1981 Apr; 24(4):370–6

Mechanism of neurotensin–induced pressor effect and tachycardia in guinea pigs. Kérouac R, et al. **Life Sci** 1981 Jun 1;28(22):2477–87

Effects of intraventricular administration of neurotensin and somatostatin on thermoregulation in the rat. Chandra A, et al. **Neuropharmacology** 1981 Jul;20(7):715–8

Neurotensin–like and somatostatin–like immunoreactivity within amacrine cells of the retina. Brecha N, et al. **Neuroscience** 1981;6(7):1329–40

Neurotensin: first report of a cortical pathway. Roberts GW, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:37–43

Electrophysiological actions of neurotensin in rat cerebellum. Marwaha J, et al. **Regul Pept** 1980 Oct;1(2):115–25

Neurotensin and substance P: differential effects on plasma cholesterol levels in conscious ovariectomized rats. Raju K, et al. **Regul Pept** 1981 Aug;2(4):265–74

Effect of neurotensin on regional intestinal blood flow in the dog. Baća I, et al. **Res Exp Med (Berl)** 1981;179(1):53–8

NEUROTIC DISORDERS

[Theoretical assessment and personal experience with the combination of psychotropic drugs and psychotherapy] Seidler C. **Z Arztl Fortbild (Jena)** 1981 May 1;75(9):412–5 **(Ger)**

NIALAMIDE

Comparisons of rotamer populations of nialamide, azaperone, and chloroquine in solid state and in solution. Migliaccio GP, et al. **J Pharm Sci** 1981 Mar;70(3):284–7

NITRAZEPAM

[Pharmaceutical use of some activated bentonites (author's transl)] Grecu I, et al. **Ann Pharm Fr** 1980;38(6):501–6 (Eng. Abstr.) **(Fre)**

NOREPINEPHRINE

Interaction at the synaptic level of fusaric acid with neurotransmitters. Fischer HD, et al. **Acta Biol Med Ger** 1980;39(8–9):935–40
Effect of oestradiol-17 beta on the metabolism of noradrenaline in brain slices of ovariectomized rats. Köster G, et al. **Acta Endocrinol (Copenh)** 1981 Sep;98(1):1–7
Dextro-phenylalanine as inhibitor of the noradrenaline release from the isolated rat hypothalamus. Pardal JF, et al. **Acta Neurol Latinoam** 1979; 25(3–4):235–48
Noradrenaline release and uptake in isolated small dense cored vesicles from rat seminal ducts. Fried G. **Acta Physiol Scand** 1981 May; 112(1):41–6
Neuronal and extraneuronal uptake of 3H-noradrenaline in rat portal vein in vitro. Hedner J, et al. **Acta Physiol Scand** 1981 Feb;111(2):171–7
Responses to catecholamines and nerve stimulation of the perfused rete tibiotarsale and associated blood vessels in the hind limb of the Mallard (Anas platyrhynchos). Midtgård U, et al. **Acta Physiol Scand** 1981 May; 112(1):77–81
Stimulatory and inhibitory effects of catecholamines and of prostaglandin E2 on human fat cell adenylate cyclase. Kather H, et al. **Adv Cyclic Nucleotide Res** 1981;14:555–62
Bradykinin effects on adrenergic transmission in the canine kidney: relation to prostaglandins. Sušić H, et al. **Am J Physiol** 1981 Sep; 241(3):R146–51
Endogenous norepinephrine release induced by tyramine modulates intestinal ion transport. Tapper EJ, et al. **Am J Physiol** 1981 Sep; 241(3):G264–9
Functional properties of noradrenergic nervous system in rat colonic mucosa: uptake of [3H]norepinephrine. Wu ZC, et al. **Am J Physiol** 1981 Aug;241(2):G137–42
The effect of pimozide on CSF norepineparine in schizophrenia. Sternberg DE, et al. **Am J Psychiatry** 1981 Aug;138(8):1045–50
Reverse-phase high-performance liquid chromatographic separation and electrochemical detection of norepinephrine, dopamine, serotonin, and related major metabolites. Kempf E, et al. **Anal Biochem** 1981 Apr; 112(2):223–31
Application of high-performance liquid chromatography with a chemiluminescence detection system to determine catecholamines in urine. Kobayashi S, et al. **Anal Biochem** 1981 Mar 15;112(1):99–104
Catecholamine excretion rates in relation to life-styles in the male population of Otmoor, Oxfordshire. Reynolds V, et al. **Ann Hum Biol** 1981 May–Jun;8(3):197–209
An analysis of the effects of apomorphine and haloperidol on the release of [3H]-dopamine and [3H]-noradrenaline from rabbit brain slices. Kelly MJ. **Arch Int Pharmacodyn Ther** 1981 Mar;250(1):18–29
Social housing conditions influence escape deficits produced by uncontrollable stress: assessment of the contribution of norepinephrine. Anisman H, et al. **Behav Neural Biol** 1981 Aug;32(4):406–27
The involvement of the locus coeruleus in memory. Prado de Carvalho L, et al. **Behav Neural Biol** 1981 Feb;31(2):173–86
Effects on fluorine analogs of norepinephrine on stimulation of cyclic adenosine 3',5'-monophosphate and binding to beta-adrenergic receptors in intact pinealocytes. Auerbach DA, et al. **Biochem Pharmacol** 1981 May 15;30(10):1085–9
No evidence for reverse trans-synaptic regulation of neuronal uptake by beta-adrenoceptors in kitten atria. Cornish EJ, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1439–42
Amfonelic acid antagonism of dopamine and norepinephrine depletion by alpha-methyl-m-tyrosine in rat brain. Fuller RW, et al. **Biochem Pharmacol** 1981 Jul 15;30(14):2025–6
Na+, K+-ATPase activity and noradrenaline turnover in brown adipose tissue of rats exhibiting diet-induced thermogenesis. Rothwell NJ, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1709–12
Adrenocortical function and plasma norepinephrine in normal human subjects. Sotsky SM, et al. **Biol Psychiatry** 1981 Jul;16(7):643–51
Habitual catecholamine excretion and its relation to habitual distress. Forsman L. **Biol Psychol** 1980 Sep;11(2):83–97
Changes in plasma catecholamine concentrations during endotracheal intubation. Russell WJ, et al. **Br J Anaesth** 1981 Aug;53(8):837–9
Isoprenaline- and noradrenaline-induced hyperpolarization of guinea-pig liver cells. Karashima T. **Br J Pharmacol** 1981 Aug;73(4):867–77
The effects of 4-aminopyridine on the isolated vas deferens and its effects on the inhibitory properties of adenosine, morphine, noradrenaline and gamma-aminobutyric acid. Stone TW. **Br J Pharmacol** 1981 Jul; 73(3):791–6
Noradrenergic innervation of serotonergic neurons in the dorsal raphe: demonstration by electron microscopic autoradiography. Baraban JM, et al. **Brain Res** 1981 Jan 5;204(1):1–11
Insulin-induced elevation of hypothalamic norepinephrine turnover persists after glucorestoration unless feeding occurs. Bellin SI, et al. **Brain Res** 1981 Aug 3;217(2):327–37
The response of individual sympathetic preganglionic neurones to microelectrophoretically applied endogenous monoamines. Coote JH, et al. **Brain Res** 1981 Jun 29;215(1–2):135–45
Noradrenaline stimulates somatostatin release from incubated slices of the amygdala and the hypothalamic preoptic area. Epelbaum J, et al. **Brain Res** 1981 Jun 29;215(1–2):393–7
Release of endogenous catecholamines from slices of hypothalamus of rats. Hamlet MA, et al. **Brain Res** 1981 Aug 3;217(2):315–25
Norepinephrine reduces excitability of single cutaneous primary afferent C-fibers in the cat spinal cord. Jeftinija S, et al. **Brain Res** 1981 Aug 31;219(2):456–63
Norepinephrine depletion alters cerebral oxidative metabolism in the 'active' state. LaManna JC, et al. **Brain Res** 1981 Jan 5; 204(1):87–101
Chemical deafferentation of the olfactory bulb: plasticity of the levels of tyrosine hydroxylase, dopamine and norepinephrine. Nadi NS, et al. **Brain Res** 1981 Jun 1;213(2):365–77
Suction lesions of the frontal cerebral cortex in the rat induce asymmetrical behavioral and catecholaminergic responses. Pearlson GD, et al. **Brain Res** 1981 Aug 10;218(1–2):233–42
Cyclic AMP-generating systems in rat hippocampal slices. Segal M, et al. **Brain Res** 1981 Jun 1;213(2):351–64
Effects of ventral tegmental area stimulation and microiontophoretic application of dopamine and norepinephrine on hypothalamic neurons. Barone FC, et al. **Brain Res Bull** 1981 Aug;7(2):181–93
Interaction between central gray and nucleus raphe magnus: role of norepinephrine. Behbehani MM, et al. **Brain Res Bull** 1981 May; 6(5):361–4
Forebrain norepinephrine and serotonin concentrations and cardiac conditioning in normal rabbits and rabbits with septal lesions. Hernández LL, et al. **Brain Res Bull** 1981 Jun;6(6):479–86
Changes in brain norepinephrine content in mice following neonatal 6-hydroxydopamine. Lovell KL. **Brain Res Bull** 1981 Jul;7(1):41–4
Regional changes in brain norepinephrine content in relation to mouse-killing behavior by rats. Yoshimura H, et al. **Brain Res Bull** 1981 Aug;7(2):151–5
Catecholamines and 5-hydroxytryptamine in photophores of Porichthys notatus. Radioenzymatic detection and radioautographic localization. Anctil M, et al. **Cell Tissue Res** 1981;219(3):557–66
Correlative light-, fluorescence- and electron-microscopic studies of catecholamine-storing cells in the adrenal medulla of the domestic fowl. Chungsamarnyart N, et al. **Cell Tissue Res** 1981;217(3):471–7
Catecholamine-storing cells in the adrenal medulla of the pre- and postnatal rat. Acetylcholinesterase as a means for early discrimination of cell types. Millar TJ, et al. **Cell Tissue Res** 1981;217(1):155–70
Prejunctional inhibition of norepinephrine release caused by acetylcholine in the human saphenous vein. Rorie DK, et al. **Circ Res** 1981 Aug; 49(2):337–41
Spread of contraction in rabbit ear artery preparations in response to stimulation by norepinephrine. Vonderlage M. **Circ Res** 1981 Sep; 49(3):600–8
Studies of diurnal changes in plasma renin activity, and plasma noradrenaline, aldosterone and cortisol concentrations in man. Lightman SL, et al. **Clin Endocrinol (Oxf)** 1981 Mar;14(3):213–23
Intraventricular administration of vasopressin and oxytocin effects the steady-state levels of serotonin, dopamine and norepinephrine in rat brain. Schwarzberg H, et al. **Endocrinol Exp (Bratisl)** 1981; 15(2):75–80
Effects of diltiazem hydrochloride on pressor and steroidogenic actions of angiotensins and norepinephrine in man. Ikeda F, et al. **Endocrinol Jpn** 1980 Dec;27(6):779–84
Electrical stimulation of mesencephalic noradrenergic pathway: effects on luteinizing hormone levels in blood of ovariectomized and ovariectomized, steroid-primed rats. Leung PC, et al. **Endocrinology** 1981 Sep;109(3):720–8
Norepinephrine and thyrotropin effects on the thyroid in vitro: simultaneous stimulation of iodide organification and antagonism of thyroxine release. Maayan ML, et al. **Endocrinology** 1981 Sep; 109(3):930–4
pH-dependence of the ATP-driven uptake of noradrenaline by bovine chromaffin-granule ghosts. Scherman D, et al. **Eur J Biochem** 1981 Jun 1;116(3):535–9
Lack of modulation by presynaptic alpha 2-adrenoceptors of adrenergic transmitters release evoked by activation of 5-hydroxytryptamine and nicotine receptors. Carr SR, et al. **Eur J Pharmacol** 1981 Jun 10; 72(1):27–34
High-affinity [3H] DMI binding is associated with neuronal noradrenaline uptake in the periphery and the central nervous system. Langer SZ, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):423–4
An interaction between prejunctional alpha-adrenoceptors and prejunctional beta-adrenoceptors. Majewski H, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):493–8
Involvement of noradrenergic and dopaminergic neurons in shock-induced jumping in rats. Nishikawa T, et al. **Eur J Pharmacol** 1981 May 22;71(4):429–36
Differential actions of mianserin and iprindole on the sensitivity of cortical neurons to noradrenaline: effect of chronic treatment. Olpe HR, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):381–5
Norepinephrine produces tension through electromechanical coupling in rabbit ear artery. Trapani A, et al. **Eur J Pharmacol** 1981 Jun 10;

72(1):87-91

The effect of noradrenaline on Na-K transport in rat cerebral cortical slices. Wu PH, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):529-31

Effect of chlorphentermine on the pulmonary disposition of norepinephrine in the isolated perfused rabbit lung. Angevine LS, et al. **Exp Lung Res** 1981 May;2(2):71-84

Inhibitory action of bradykinin on release of the adrenergic transmitter in the isolated lapine kidney. Malik KU, et al. **Experientia** 1981 May 15;37(5):496-7

Thermogenic response as the function of extravascular influx of infused noradrenaline. Mejsnar J, et al. **Experientia** 1981 May 15;37(5):482-3

The effect of drugs on accumulation of exogenous norepinephrine in nervous tissue cultured in vitro. IV. The effect of clonidine. Szydłowska H, et al. **Folia Histochem Cytochem (Krakow)** 1981;19(2):93-8

Differential transmural constrictor response to norepinephrine in rabbit carotid artery. Flaim SF, et al. **Gen Pharmacol** 1981;12(4):295-301

Thyrotropin-releasing hormone increases plasma norepinephrine in man. Morley JE, et al. **Horm Res** 1981;14(1):18-23

Effects of exposure to trichloroethylene and tetrachloroethylene on the contents of acetylcholine, dopamine, norepinephrine and serotonin in rat brain. Honma T, et al. **Ind Health** 1980;18(4):171-8

The effect of light exercise on the plasma superoxide dismutase activity and on the plasma noradrenaline concentration. Minami M, et al. **Ind Health** 1981;19(2):133-8

Reduced norepinephrine response to dynamic exercise in human subjects during O2 breathing. Hesse B, et al. **J Appl Physiol** 1981 Jul; 51(1):176-8

Effects of epinephrine and norepinephrine infusion on lung fluid balance in sheep. Minnear FL, et al. **J Appl Physiol** 1981 Jun;50(6):1353-7

Effects of noradrenergic and serotonergic neurons on blood pressure, heart rate and baroreceptor-heart rate reflex of the conscious rabbit. Korner PI, et al. **J Auton Nerv Syst** 1981 Apr;3(2-4):511-23

The relation of plasma norepinephrine and epinephrine levels over time in humans. Levin BE, et al. **J Auton Nerv Syst** 1980 Dec; 2(4):315-25

Noradrenergic innervation of the villi of rat jejunum. Thomas EM, et al. **J Auton Nerv Syst** 1981 Feb;3(1):25-9

Effects of L-dopa on dopamine and norepinephrine concentrations in rat brain assessed by gas chromatography. Doshi PS, et al. **J Chromatogr** 1981 Jun 19;210(3):505-11

Some observations on the catecholaminergic innervation of the intermediate zone of the thoracolumbar spinal cord of the cat. McLachlan EM, et al. **J Comp Neurol** 1981 Aug 20;200(4):529-44

An ultrastructural and biochemical analysis of norepinephrine-containing varicosities in the cerebral cortex of the turtle Pseudemys. Ouimet CC, et al. **J Comp Neurol** 1981 Jan 10;195(2):289-304

Effect of gonadectomy on the concentrations of catecholamines in discrete areas of the diencephalon of the domestic fowl. Knight PG, et al. **J Endocrinol** 1981 Jun;89(3):389-97

Ultrastructural demonstration of noradrenergic synapses in the rat central nervous system by dopamine-beta-hydroxylase immunocytochemistry. Olschowka JA, et al. **J Histochem Cytochem** 1981 Feb;29(2):271-80

Biochemical variability in a tem sports situation. Biersner RJ, et al. **J Human Stress** 1981 Sep;7(3):12-7

Catecholamine and cortisol excretion patterns in three-year-old children and their parents. Lundberg U, et al. **J Human Stress** 1981 Sep; 7(3):3-11

Involvement of brain monoamines in the delta-9-tetrahydrocannabinol-induced reduction of hippocampal choline uptake. Lindamood C 3d, et al. **J Neurochem** 1981 Sep; 37(3):788-91

Diurnal variations in monoamine contents in discrete brain regions of the mongolian gerbil (Meriones unguiculatus). Matsumoto M, et al. **J Neurochem** 1981 Sep;37(3):792-4

The development of pre- and postsynaptic components of the noradrenergic system in the rat cerebellum. Waddington G, et al. **J Neurochem** 1981 Sep;37(3):576-81

Neuronal responses of the globus pallidus to systemic administration of d-amphetamine: investigation of the involvement of dopamine, norepinephrine, and serotonin. Bergstrom DA, et al. **J Neurosci** 1981 Mar;1(3):292-9

High-performance liquid chromatography with electrochemical detection as a highly efficient tool for studying catecholaminergic systems. I. Quantification of noradrenaline, adrenaline and dopamine in cultured adrenal medullary cells. Müller TH, et al. **J Neurosci Methods** 1981 Jun;4(1):39-52

Effect of cocaine on contractile responses to noradrenaline of canine isolated mesenteric vein. O'Connor PC, et al. **J Pharm Pharmacol** 1981 Jan;33(1):55-8

Effect of cocaine on noradrenaline contractions of mesenteric vein: pre or postjunctional mechanism? O'Connor PC, et al. **J Pharm Pharmacol** 1981 Jan;33(1):58-60

Effects of norepinephrine on pineal tryptophan hydroxylase, using an improved [14C]CO2-trapping microtechnique. Chan A, et al. **J Pharmacol Methods** 1981 Aug;6(1):13-20

Site(s) and ionic basis of alpha-autoinhibition and facilitation of '3H'noradrenaline secretion in guinea-pig vas deferens. Alberts P, et al. **J Physiol (Lond)** 1981 Mar;312:297-334

The effect of adrenaline and noradrenaline on coronary vascular reserve in the dog. Creates MS, et al. **J Physiol (Lond)** 1980 Dec; 309:557-68

The influence of the infusion of noradrenaline on plasma cortisol levels in man. Few JD, et al. **J Physiol (Lond)** 1980 Dec;309:375-89

The release of adenosine and inosine from canine subcutaneous adipose tissue by nerve stimulation and noradrenaline. Fredholm BB, et al. **J Physiol (Lond)** 1981;313:351-67

Localization of specialized noradrenaline receptors at neuromuscular junctions on arterioles of the guinea-pig. Hirst GD, et al. **J Physiol (Lond)** 1981;313:343-50

Note on estimating catecholamines in urine sampled after 75-min periods of mental work and inactivity. Forsman L. **J Psychosom Res** 1981; 25(3):223-5

The effect of catecholamines or sodium lactate on blood lactate distribution in the rat. Aragno R. **J Sports Med Phys Fitness** 1981 Mar; 21(1):7-14

Pre- and postsynaptic adrenergic activation by norepinephrine reuptake inhibitors in the field-stimulated rat vas deferens. Lotti VJ, et al. **Life Sci** 1981 Aug 10;29(6):633-9

Stimulation of prostaglandin E2-synthesis by noradrenaline in primary cell cultures from rabbit splenic pulpa is mediated by atypical alpha-adrenoceptors. Brückner-Schmidt R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb;316(1):1-7

The positive inotropic effect of (-)-noradrenaline and (+/-)-isoprenaline after chemical sympathectomy: evidence in favour of differences at a postsynaptic site. Ebner F, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb;316(1):8-18

In vitro studies on 6-fluoronoradrenaline at several peripheral sympathetic neuroeffector junctions. Shepperson NB, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Aug;317(1):1-4

Enhancement of 3H-noradrenaline overflow from cardiac sympathetic nerves by low Ca and tetraethylammonium. Wakade AR, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jul;316(4):273-7

Norepinephrine uptake in aging adrenergic nerve terminals. Hoffman DW, et al. **Neurobiol Aging** 1980 Summer;1(1):65-8

The effect of hypoxia on monoamine levels in discrete regions of aged rat brain. Roubein IF, et al. **Neurobiol Aging** 1981 Spring;2(1):37-40

Importance of norepinephrine alpha 2-receptor activation for morphine-induced rat growth hormone secretion. Eriksson E, et al. **Neuroendocrinology** 1981 Aug;33(2):91-6

Adrenal medullary secretory response to pontine and mesencephalic stimulation in the rat. Matsui H. **Neuroendocrinology** 1981 Aug; 33(2):84-7

Effect of injury to the serotoninergic and noradrenergic brain systems on food and defensive conditioned reflexes in rats. Gromova EA, et al. **Neurosci Behav Physiol** 1981 Jan-Feb;11(1):10-5

Brain levels of noradrenalin, dopamine, and serotonin in rats with different levels of motor activity. Semenova TP, et al. **Neurosci Behav Physiol** 1981 Mar-Apr;11(2):153-5

Recovery cycles of visual cortical primary responses during pharmacological and electrical intervention on monoaminergic systems of the rat brain. Vorob'ev VV, et al. **Neurosci Behav Physiol** 1981 Mar-Apr;11(2):129-33

The effects of lesions of lateral tegmental noradrenergic neurons on components of sexual behavior and pseudopregnancy in female rats. Hansen S, et al. **Neuroscience** 1981;6(6):1105-17

Behavioral assessment of norepinephrine and serotonin function and interaction in the hippocampal formation. Gage FH, et al. **Pharmacol Biochem Behav** 1981 Jun;14(6):815-21

A new approach to the role of noradrenaline in learning: problem-solving in the marmoset after alpha-noradrenergic receptor blockade. Ridley RM, et al. **Pharmacol Biochem Behav** 1981 Jun;14(6):849-55

Diltiazem and verapamil inhibit norepinephrine-stimulated 45Ca uptake in rabbit aorta. Flaim SF, et al. **Pharmacology** 1981;22(5):286-93

Compartmental analysis of tyramine-induced norepinephrine depletion. Rapoport RM, et al. **Pharmacology** 1981;22(4):235-42

Rewarding effect of noradrenergic stimulation of the amygdala in food deprived rats. Jurkowlaniec E, et al. **Physiol Behav** 1981 Jul; 27(1):27-31

The central noradrenergic transmission and the locus coeruleus: a review of the data, and their implications for neurotransmission and neuromodulation. van Dongen PA. **Prog Neurobiol** 1981; 16(2):117-43 (303 ref.)

Effects of 6-hydroxydopamine lesions of locus coeruleus on startle in rats. Adams LM, et al. **Psychopharmacology (Berlin)** 1981; 73(4):394-8

Noradrenergic and dopaminergic interactions in escape behavior: analysis of uncontrollable stress effects. Anisman H, et al. **Psychopharmacology (Berlin)** 1981;74(3):263-8

Differences in presynaptic alpha-blockade, noradrenaline uptake inhibition, and potential antidepressant activity between (+)- and (-)mianserin. Schoemaker H, et al. **Psychopharmacology (Berlin)** 1981; 74(2):137-42

Relationships between sex-related psychological characteristics during adolescence and catecholamine excretion during achievement stress. Rauste-von Wright M, et al. **Psychophysiology** 1981 Jul;18(4):362-70

MK-771 enhances the turnover of norepinephrine in brain. Rastogi RB, et al. **Res Commun Chem Pathol Pharmacol** 1981 Jul;33(1):187-90

Biosynthesis of biopterin: adrenergic cyclic adenosine monophosphate-dependent inhibition in the pineal gland. Kapatos G, et al. **Science** 1981 Sep 4;213(4512):1129-31

Cerebroventricular propranolol elevates cerebrospinal fluid norepinephrine and lowers blood pressure. Tackett RL, et al. **Science** 1981 Aug 21;213(4510):911-3

Effect of acetylcholine and catecholamines on the enterochromaffin-like cells of the stomach. Sano M, et al. **Surg Gynecol Obstet** 1981 Sep; 153(3):337-40

Similar regulatory mechanism underlying 3H-noradrenaline release from isolated hypothalamus and perfused tail artery or the rat by Latrodectus antheratus (black widow spider) venom gland extract and by potassium. Pardal JF, et al. **Toxicon** 1981;19(2):249-54

[Plasma catecholamines, metabolic substrates, aerobic and anaerobic capacity during graduated treadmill and bicycle ergometer exercise (author's transl)] Lehmann M, et al. **Klin Wochenschr** 1981 Jun 1; 59(11):553-9 (Eng. Abstr.) **(Ger)**

[Metabolic effects of intravenous noradrenaline in metabolically healthy humans] Möricke R, et al. **Z Gesamte Inn Med** 1981 Jul 1; 36(13):433-43 (Eng. Abstr.) **(Ger)**

[Urinary excretion of MHPG in endogenous depression. Clinico-therapeutic index] Roccatagliata G, et al. **Minerva Psichiatr** 1981 Apr-Jun;22(2):75-8 (Eng. Abstr.) **(Ita)**

[Norepinephrine content in the inferior turbinate of the patients with nasal allergy (author's transl)] Fujitani T, et al. **Nippon Jibiinkoka Gakkai Kaiho** 1981 Feb;84(2):168-73 (Eng. Abstr.) **(Jpn)**

[Effects of tetragastrin on catecholamines in gastric juice and gastric tissues in rats (author's transl)] Baba M, et al. **Nippon Shokakibyo Gakkai Zasshi** 1981 Jun;78(6):1191-7 (Eng. Abstr.) **(Jpn)**

[Adrenaline and noradrenaline levels before and after heart catheterization] Rumiński W, et al. **Pol Tyg Lek** 1981 Mar 30; 36(13):461-3 (Eng. Abstr.) **(Pol)**

[Role of noradrenaline in luteinizing hormone secretion] Adamskaia EI, et al. **Biull Eksp Biol Med** 1981 Jun;91(6):730-3 (Eng. Abstr.) **(Rus)**

[Technic for simultaneous recording of the uptake and secretion of 14C-noradrenaline by rat brain synaptosomes] Bazian AS, et al. **Biull Eksp Biol Med** 1981 Mar;91(3):377-9 (Eng. Abstr.) **(Rus)**

[Regulation of the functioning of molluscan neuron cholinoreceptors by succinate and noradrenaline] Andreev AA, et al. **Dokl Akad Nauk SSSR** 1981;258(6):1466-9 **(Rus)**

[Role of noradrenaline-sensitive neurons of the preoptic area in regulating luteinizing hormone release] Babichev VN, et al. **Fiziol Zh SSSR** 1981 Jun;67(6):809-15 (Eng. Abstr.) **(Rus)**

[Plasma catecholamines of August and Wistar strain rats subjected to emotional stress] Kvetnanskiĭ R, et al. **Fiziol Zh SSSR** 1981 Apr; 67(4):516-23 (Eng. Abstr.) **(Rus)**

[Effects of certain biologically active compounds and bivalent cations on lactate and malate dehydrogenase activities in cerebral cellular fractions] Bdovichenko LM. **Ukr Biokhim Zh** 1981 May-Jun; 53(3):66-70 (Eng. Abstr.) **(Rus)**

[Effect of scopolamine on temporary connection formation and fixation in rats with altered brain noradrenaline content] Orlova NV. **Zh Vyssh Nerv Deiat** 1981 May-Jun;31(3):571-6 (Eng. Abstr.) **(Rus)**

[Participation of hypothalamic noradrenergic structures in the reproduction of conditioned 'passive' avoidance reactions] Tolochko ZS. **Zh Vyssh Nerv Deiat** 1981;31(2):267-70 (Eng. Abstr.) **(Rus)**

NORMETANEPHRINE

A radioenzymatic method for determination of normetanephrine in blood plasma. Nagel-Hiemke M, et al. **J Biochem Biophys Methods** 1981 Jun; 4(5-6):255-9

Concomitant analysis of normetanephrine and 3-methoxytyramine in brain: a new gas-liquid chromatography procedure. LeGatt DF, et al. **Res Commun Chem Pathol Pharmacol** 1981 Jul;33(1):61-8

NORTRIPTYLINE

Fatal nortriptyline overdose, plasma levels, and in vivo methylation of tricyclic antidepressants. Rudorfer MV, et al. **Am J Psychiatry** 1981 Jul;138(7):982-3

The pharmacokinetics of nortriptyline in patients with chronic renal failure. Dawling S, et al. **Br J Clin Pharmacol** 1981 Jul;12(1):39-45

E- and Z-10-hydroxylation of nortriptyline: relationship to polymorphic debrisoquine hydroxylation. Mellström B, et al. **Clin Pharmacol Ther** 1981 Aug;30(2):189-93

Amitriptyline and nortriptyline plasma levels monitoring. Perspective in clinical practice. Corona GL, et al. **Commun Psychopharmacol** 1980; 4(4):309-16

Reliability of tricyclic antidepressant levels — further questions [letter] Bank RL, et al. **J Clin Psychiatry** 1981 Sep;42(9):364

Effects of nortriptyline treatment on learned helplessness in the rat. Telner JI, et al. **Pharmacol Biochem Behav** 1981 Jun;14(6):823-6

Flupenthixol versus combined fluphenazine-nortriptyline in depressive illness.. Conway JF. **Practitioner** 1981 Mar;225(1353):400-4

Amitriptyline pharmacokinetics. A crossover study with single doses of amitriptyline and nortriptyline. Burch JE, et al. **Psychopharmacology (Berlin)** 1981;74(1):35-42

OBSESSIVE-COMPULSIVE DISORDER

A comparison of phenelzine and imipramine in an obsessive-compulsive patient. Isberg RS. **Am J Psychiatry** 1981 Sep;138(9):1250-1

Rapid response of severe obsessive-compulsive disorder to tranylcypromine. Jenike MA. **Am J Psychiatry** 1981 Sep; 138(9):1249-50

Double-blind comparative study of clomipramine and amitriptyline in obsessive neurosis. Ananth J, et al. **Prog Neuropsychopharmacol** 1981; 5(3):257-62

ORGANIC MENTAL DISORDERS, PSYCHOTIC

[Role of psychopharmacotherapy in the treatment of late middle-aged and elderly patients with organic psychotic syndromes] Saarma IuM, et al. **Vestn Akad Med Nauk SSSR** 1980;(12):50-3 (Eng. Abstr.) **(Rus)**

OXALATES

[Prevention effect of some substances on experimental oxalic calculosis in the frog] Sorrentino F, et al. **Minerva Nefrol** 1979 Jul-Sep; 26(3):329-31 (Eng. Abstr.) **(Ita)**

OXAZEPAM

Specific binding of racemic oxazepam esters to rat brain synaptosomes and the influence of bioactivation by esterases. Maksay G, et al. **Arzneimittelforsch** 1981;31(6):979-81

Benzodiazepine structure versus reactivity with EMIT oxazepam antibody. Budd RD. **Clin Toxicol** 1981 May;18(5):643-55

Disposition of oxazepam in relation to age, sex, and cigarette smoking. Ochs HR, et al. **Klin Wochenschr** 1981 Aug 17;59(16):899-903

[Pharmaceutical use of some activated bentonites (author's transl)] Grecu I, et al. **Ann Pharm Fr** 1980;38(6):501-6 (Eng. Abstr.) **(Fre)**

PAIRED-ASSOCIATE LEARNING

Methylphenidate impairs learning and memory in normal adults. Wetzel CD, et al. **Behav Neural Biol** 1981 Apr;31(4):413-24

PARASYMPATHOMIMETICS

The influence of microinjections of cholinomimetics into hypothalamus on the locomotor activity of rats. Plech A. **Agressologie** 1979; 20(D):279-82

Influence of castration upon the seminal vesicle response to parasympathomimetic drugs. Porto CS, et al. **Arch Int Pharmacodyn Ther** 1981 Apr;250(2):204-11

Evidence of overadditive interaction between fenoterol and ipratropium bromide in the counteraction of cholinomimetic-induced tracheobronchial contractions. Bongrani S, et al. **Arzneimittelforsch** 1981;31(6):970-3

Effect of antimuscarinic agents on the contractile responses to cholinomimetics in the rat anococcygeus muscle. Doggrell SA. **Br J Pharmacol** 1981 Aug;73(4):829-35

Cholinergic receptor interactions and their effects on long-term memory processing. Flood JF, et al. **Brain Res** 1981 Jun 29;215(1-2):177-85

Vasoconstriction produced by intracoronary cholinomimetic drugs in isolated donor-perfused hearts of rhesus monkeys: comparison with pig, dog, and rabbit hearts. Sakai K. **J Cardiovasc Pharmacol** 1981 May-Jun; 3(3):500-9

Disruption and facilitation of cue discrimination in the rat by cholinergic agents. Rick JT, et al. **Neuropharmacology** 1981 Aug;20(8):747-52

Chronic haloperidol treatment fails to alter the anorexic actions of dopaminergic agonists and cholinergic drugs. Hynes MD, et al. **Prog Neuropsychopharmacol** 1981;5(3):271-5

[Cholinergics and anticholinergics] Advenier C, et al. **Rev Prat** 1981 Aug; 31(37):2663-8 (Eng. Abstr.) **(Fre)**

PARGYLINE

Influence of harmaline on the ability of pargyline to alter catecholamine metabolism in rats. Fuller RW, et al. **Biochem Pharmacol** 1981 Jun 1; 30(11):1295-8

Differences in the structure of A and B forms of human monoamine oxidase. Cawthon RM, et al. **J Neurochem** 1981 Aug;37(2):363-72

The acetylenic monoamine oxidase inhibitors clorgyline, deprenyl, pargyline and J-508: their properties and applications. Fowler CJ, et al. **J Pharm Pharmacol** 1981 Jun;33(6):341–7 (83 ref.)

Postmortem changes of 5-hydroxytryptamine and 5-hydroxyindoleacetic acid in mouse brain and their prevention by pargyline and microwave irradiation. Van Wijk M, et al. **Neurochem Res** 1981 Apr; 6(4):425–30

PEMOLINE

Effects of Mg-pemoline on the central catecholaminergic system. Molina VA, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):66–79

PENTOBARBITAL

Cimetidine hydrochloride compatibility with preoperative medications. Yuhas EM, et al. **Am J Hosp Pharm** 1981 Aug;38(8):1173–4

Canine cerebral metabolic tolerance during 24 hours deep pentobarbital anesthesia. Gronert GA, et al. **Anesthesiology** 1981 Aug;55(2):110–3

Long-term effect of pentobarbital anesthesia on neophobia in the rat. McGee R, et al. **Behav Neural Biol** 1981 Jul;32(3):376–9

Effects of pentobarbital on delayed alternation performance. Terry WS, et al. **Behav Neural Biol** 1981 Jul;32(3):380–5

Effects of chronic administration of pentobarbital or morphine on the brain microsomal cytochrome P-450 system. Nabeshima T, et al. **Biochem Pharmacol** 1981 May 15;30(10):1142–5

The effects of thyrotropin releasing hormone on pentobarbital tolerance. Bhargava HN. **Eur J Pharmacol** 1981 Jun 10;72(1):63–8

Effect of monoamine oxidase inhibitors on codeine disposition and pentobarbitone sleep-times in the rat. Findlay JW, et al. **J Pharm Pharmacol** 1981 Jan;33(1):45–7

Pentobarbital enhances [3H]diazepam binding to soluble receptors at the benzodiazepine--GABA-receptor-ionophore complex. Davis WC, et al. **Neurosci Lett** 1981 May 6;23(2):209–13

Direct action of pentobarbitone in potentiating the responses to GABA of rat dorsal root ganglion neurones in vitro. Headley PM, et al. **Neurosci Lett** 1981 Jul 17;24(3):273–80

Effect of acute or chronic pentobarbital administration on the steady state levels and the turnover rates of catecholamines in discrete brain areas of mice. Nabeshima T, et al. **Prog Neuropsychopharmacol** 1981; 5(2):121–8

Use of simple tasks to test for impairment of complex skills by a sedative. Ellinwood EH Jr, et al. **Psychopharmacology (Berlin)** 1981; 73(4):350–4

[Age and the effects of barbiturates on rat liver microsome oxidative enzymes] Paramonova GI. **Farmakol Toksikol** 1981 Jan–Feb; 44(1):98–101 (Eng. Abstr.) **(Rus)**

PEPTIDES

beta-Adrenergic stimulation of the release of ACTH- and LPH-related peptides from the pars intermedia of the rat pituitary gland. Tilders FJ, et al. **Acta Endocrinol (Copenh)** 1981;97(3):343–51

Stimulation of gastrin and somatostatin secretion from the isolated rat stomach by bombesin. DuVal JW, et al. **Am J Physiol** 1981 Sep; 241(3):G242–7

Nanosecond fluorometry and the luminescence of biological macromolecules. Brand L, et al. **Ann NY Acad Sci** 1981; 366:197–207

Comparative histochemistry as a springboard for the discovery of biogenic amines and active peptides in molluscan tissues and amphibian skin. Erspamer V. **Basic Appl Histochem** 1981;25(1):3–14

Epidermal growth factor stimulates monovalent cation transport in isolated rat hepatocytes. Fehlmann M, et al. **Biochem Biophys Res Commun** 1981 May 15;100(1):254–60

Laser chemically induced dynamic nuclear polarization study of the reaction between photoexcited flavins and tryptophan derivatives at 360 MHz. McCord EF, et al. **Biochemistry** 1981 May;20(10):2880–8

Systematic variation in bond lengths of peptides. Chakrabarti P, et al. **Biochim Biophys Acta** 1981 Aug 28;670(1):134–7

Excitatory effect of a new polypeptide (anthopleurin-B) from sea anemone on the guinea-pig vas deferens. Norton TR, et al. **Br J Pharmacol** 1981 Sep;74(1):23–8

Thermoregulatory effects of centrally administered bombesin, bradykinin, and methionine-enkephalin. Francesconi R, et al. **Brain Res Bull** 1981 Jul;7(1):63–8

Epidermal growth factor induces rapid tyrosine phosphorylation of proteins in A431 human tumor cells. Hunter T, et al. **Cell** 1981 Jun; 24(3):741–52

Immunohistochemical localization of polypeptide hormones in endocrine cells of the digestive tract of Branchiostoma lanceolatum. Reinecke M. **Cell Tissue Res** 1981;219(3):445–56

Isolation of peptides from uremic plasma that inhibit phenytoin binding to normal plasma proteins. Kinniburgh DW, et al. **Clin Pharmacol Ther** 1981 Aug;30(2):276–80

Inhibition of pituitary-testicular axis response to gonadotropin releasing hormone by pineal treatment. Damian E, et al. **Endocrinologie** 1981 Apr–Jun;19(2):93–6

Hormonal regulation of epidermal growth factor and protease in the submandibular gland of the adult mouse. Gresik EW, et al. **Endocrinology** 1981 Sep;109(3):924–9

Effect of thyroxine, testosterone, and corticosterone on nerve growth factor (NGF) and epidermal growth factor (EGF) concentrations in adult female mouse submaxillary gland: dissociation of NGF and EGF responses. Walker P, et al. **Endocrinology** 1981 Aug;109(2):582–7

The contractile effect of bombesin on the rat isolated urinary bladder. Abdel-Hakim AM, et al. **Eur J Pharmacol** 1981 Mar 12; 70(2):167–73

Bombesin, calcitonin and leu-enkephalin immunoreactivity in endocrine cells of human lung. Cutz E, et al. **Experientia** 1981 Jul 15; 37(7):765–7

Hypothalamic peptides: central nervous system control of visceral functions. Brown M, et al. **Fed Proc** 1981 Sep;40(11):2565–9 (32 ref.)

Systematic separation of medium-sized biologically active peptides by high-performance liquid chromatography. Mabuchi H, et al. **J Chromatogr** 1981 Aug 28;213(2):275–86

The distribution of nine peptides in rat spinal cord with special emphasis on the substantia gelatinosa and on the area around the central canal (lamina X). Gibson SJ, et al. **J Comp Neurol** 1981 Sep 1; 201(1):65–79

Hypothalamic hypophysiotrophic peptides, known and unknown. The Sir Henry Dale lecture for 1980. Guillemin R. **J Endocrinol** 1981 Jul; 90(1):3p–10p (38 ref.)

The expression of anti-poly(LGlu60, LPhe40) idiotypic determinants dictated by the gene products in the major histocompatibility complex. Babu UM, et al. **J Exp Med** 1981 Sep 1;154(3):649–58

Structure of murine Ia antigens. Two dimensional electrophoretic analyses and high pressure liquid chromatography tryptic peptide maps of products of the I-A and I-E subregions and of an associated invariant polypeptide. McMillan M, et al. **J Exp Med** 1981 Apr 1; 153(4):936–50

Synthesis of peptides by the solid-phase method. 6. Neurotensin, fragments, and analogues. St-Pierre S, et al. **J Med Chem** 1981 Apr; 24(4):370–6

Behavioral and neurochemical effects of the new opioid peptide dynorphin--(1–13): comparison with other neuropeptides. Zwiers H, et al. **Life Sci** 1981 Jun 1;28(22):2545–51

Human transforming growth factors induce tyrosine phosphorylation of EGF receptors. Reynolds FH Jr, et al. **Nature** 1981 Jul 16; 292(5820):259–62

Somatostatin-like immunoreactivity in the facial, glossopharyngeal and vagal lobes of the carp. Tohyama M, et al. **Neurosci Lett** 1981 Jul 17; 24(3):233–6

Neurotensin-like and somatostatin-like immunoreactivity within amacrine cells of the retina. Brecha N, et al. **Neuroscience** 1981;6(7):1329–40

Neuropeptides and brain cAMP and phosphoproteins. Wiegant VM, et al. **Pharmacol Ther** 1981;12(3):463–90

Peptides as neurotransmitters: focus on the enkephalins and endorphins. Miller RJ. **Pharmacol Ther [B]** 1981;12(1):73–108 (214 ref.)

The effect of somatostatin and 16,16-dimethyl-prostaglandin E2 on bombesin-stimulated canine gastric acid, plasma gastrin and pancreatic polypeptide secretion. Materia A, et al. **Regul Pept** 1981 Jan; 1(4):297–305

Stimulation of canine pancreatic polypeptide, gastrin, and gastric acid secretion by ranatensin, litorin, bombesin nonapeptide and substance P. Modlin IM, et al. **Regul Pept** 1981 Jan;1(4):279–88

Effect of bombesin upon plasma somatostatin-like immunoreactivity, insulin and glucagon in normal and chemically sympathectomized dogs. Schusdziarra V, et al. **Regul Pept** 1980 Oct;1(2):89–96

[Immunohistochemical localization of neuropeptides in mammalian brain (author's transl)] Zhang ZX, et al. **Sheng Li Ko Hsueh Chin Chan** 1980 Apr;11(4):342–7 **(Chi)**

[The relation between nerves and gastrointestinal peptides] Zhu WY. **Sheng Li Ko Hsueh Chin Chan** 1980 Mar;11(3):259–62 **(Chi)**

[Present status of studies on peptides with biological activity] Suzuki T. **Nippon Rinsho** 1980 Oct;38(10):4230–7 (42 ref.) **(Jpn)**

[Peptides as carriers of information in psychiatric diseases] Reichelt KL. **Nord Med** 1980 Nov;95(11):283–6 **(Nor)**

[Effects of cerebral, hypothalamic and hypophyseal peptides on the central nervous system] Comaru-Schally AM, et al. **Medicina (B Aires)** 1981; 41(2):244–56 (108 ref.) **(Spa)**

PERCEPTUAL DISORDERS

Span of apprehension deficits during the postpsychotic stages of schizophrenia. A replication and extension. Asarnow RF, et al. **Arch Gen Psychiatry** 1981 Sep;38(9):1006–11

PERPHENAZINE

[On the question of differences between therapeutic responses after particular neuroleptics in comparison to perphenazine in schizophrenics (author's transl)] Náhunek K, et al. **Cesk Psychiatr** 1981 Feb; 77(1):25–30 (Eng. Abstr.) **(Cze)**

PERSONALITY INVENTORY

[Effect of phenobarbital on self-ratings of healthy subjects in comparison to the objective impairment of their performance] Walther H, et al. **Acta Biol Med Ger** 1980;39(8-9):949-60 (Eng. Abstr.) **(Ger)**

PHENCYCLIDINE

Color test for detection of 1-piperidinocyclohexanecarbonitrile (PCC) in illicit phencyclidine. Dulik DM, et al. **Clin Toxicol** 1981 Jun; 18(6):737-42

The metabolism of phencyclidine by rabbit liver preparations. Kammerer RC, et al. **Drug Metab Dispos** 1981 May-Jun;9(3):274-8

Stimulation of synaptosomal tyrosine hydroxylation by phencyclidine in vitro. Vickroy TW, et al. **Eur J Pharmacol** 1981 May 22; 71(4):463-73

Simultaneous determination of phencyclidine and monohydroxylated metabolites in urine of man by gas chromatography-mass fragmentography with methane chemical ionization. Cone EJ, et al. **J Chromatogr** 1981 May 8;223(2):331-9

Detection of phencyclidine in hair. Baumgartner AM, et al. **J Forensic Sci** 1981 Jul;26(3):576-81

Mammalian metabolism of phencyclidine. Baker JK, et al. **J Med Chem** 1981 Jun;24(6):666-9

Electrophysiological effects of phencyclidine on rat hippocampal pyramidal neurons. Bickford PC, et al. **Neuropharmacology** 1981 Aug; 20(8):733-42

Behavioral effects of phencyclidine in the developing cat. Levine MS, et al. **Neuropharmacology** 1981 Aug;20(8):743-5

Chronic phencyclidine induced changes in rat central cholinergic receptor regulation. Ward DP, et al. **Proc West Pharmacol Soc** 1981;24:3-4

Doxylamine: a cause for false-positive gas chromatographic assay for phencyclidine. Schaldenbrand JD, et al. **Ther Drug Monit** 1981; 3(2):181-3

PHENELZINE

A comparison of phenelzine and imipramine in an obsessive-compulsive patient. Isberg RS. **Am J Psychiatry** 1981 Sep;138(9):1250-1

PHENETHYLAMINES

Physico-chemical properties of phenethylamines and their uptake into synaptic vesicles of the caudate nucleus. Lentzen H, et al. **Biochem Pharmacol** 1981 Jul 1;30(13):1759-64

The formation of azoxy-2-phenylethane during the biological oxidation of phenylethylamine by rabbit liver microsomes. Fiala ES, et al. **Carcinogenesis** 1981;2(3):165-73

Studies on phenethylamine hallucinogens. 2. Conformations of arylmethoxyl groups using 13C NMR. Knittel JJ, et al. **J Med Chem** 1981 Jul;24(7):906-9

Alteration of dopamine synthesis in rat striatum subsequent to selective type A monoamine oxidase inhibition. Schoepp DD, et al. **J Neurochem** 1981 Aug;37(2):527-30

Substrate- and stereoselective inhibitor of human brain monoamine oxidase by 4-dimethylamino-alpha, 2-dimethylphenethylamine (FLA 336). Fowler CJ, et al. **J Pharm Pharmacol** 1981 Jun;33(6):403-6

The acetylenic monoamine oxidase inhibitors clorgyline, deprenyl, pargyline and J-508: their properties and applications. Fowler CJ, et al. **J Pharm Pharmacol** 1981 Jun;33(6):341-7 (83 ref.)

GLC analysis of phenylalkyl amines using nitrogen detector. Javaid JI, et al. **J Pharm Sci** 1981 Jul;70(7):813-5

Studies on beta-phenylethylamine deamination by human placental monoamine oxidase. Oguchi K, et al. **Jpn J Pharmacol** 1981 Feb; 31(1):7-14

Central action of phenylethylamine in rats. Jagiello-Wójtowicz E. **Pol J Pharmacol Pharm** 1981 Jan-Feb;33(1):59-71

[Hemodynamic effects of Praxinor on the peripheral circulation (author's transl)] Oliva I, et al. **Sem Hop Paris** 1981 May 18-25; 57(19-20):1034-8 (Eng. Abstr.) **(Fre)**

[Effect of pyrazidole and deprenyl on monoamine oxidase in the rat intestine] Mashkovskiĭ MD, et al. **Biull Eksp Biol Med** 1981 Mar; 91(3):309-11 (Eng. Abstr.) **(Rus)**

PHENOBARBITAL

Enzyme inducer effects after liver denervation in the rat. Frenkl R, et al. **Acta Physiol Acad Sci Hung** 1981;57(1):47-50

Adverse effects of phenobarbital on morphological and biochemical development of fetal mouse spinal cord neurons in culture. Bergey GK, et al. **Ann Neurol** 1981 Jun;9(6):584-9

Phenobarbital treatments lower DDT body burden in rhesus monkeys. Ferguson PW, et al. **Arch Environ Contam Toxicol** 1981; 10(3):263-70

Effect of phenobarbital pretreatment on benzene biotransformation in the rat. II. 9,000 g supernatant and isolated perfused liver versus living rat. Gut I, et al. **Arch Toxicol** 1981 Mar;47(1):13-24

Testosterone oxidation by rat liver microsomes: effects of phenobarbital pretreatment and the detection of seven metabolites by HPLC. van der Hoeven T. **Biochem Biophys Res Commun** 1981 Jun 16; 100(3):1285-91

Inhibition of microsomal phenobarbital metabolism by valproic acid. Kapetanović IM, et al. **Biochem Pharmacol** 1981 Jun 1;30(11):1361-3

Comparison of gamma-glutamyl transferase induction by phenobarbital in the rat, guinea pig and rabbit. Rooms MW, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1563-71

Effects of phenobarbital, 3-methylcholanthrene and beta-naphthoflavone pretreatment on mouse liver microsomal enzymes and on metabolite patterns of benzo[a]pyrene. Wang IY. **Biochem Pharmacol** 1981 Jun 1; 30(11):1337-43

The effect of phenobarbital and 3'-methyl-N,N-dimethyl-4-aminoazobenzene administration on catalytic, binding and immunological properties of ligandin subunits in rat liver. Ohmi N, et al. **Biochim Biophys Acta** 1981 Jul; 675(2):276-80

In vitro cellular adaptation of serotonergic processes after chronic central phenobarbital administration. Lyness WH, et al. **Brain Res** 1981 Jan 5;204(1):248-52

Calcium uptake mechanisms affected by some convulsant and anticonvulsant drugs. Pincus JH, et al. **Brain Res** 1981 Jul 27; 217(1):119-27

Induction by phenobarbital of ornithine decarboxylase activity in rat liver after initiation with diethylnitrosamine. Yanagi S, et al. **Cancer Lett** 1981 Mar;12(1-2):87-91

Apparent differential response of nuclear envelope cytochrome P-450 following phenobarbital induction arising from a preferential loss during gradient purification. Clawson GA, et al. **Cancer Res** 1981 Aug; 41(8):3122-7

Polyhalogenated biphenyls and phenobarbital: evaluation as inducers of drug metabolizing enzymes in the sheepshead, Archosargus probatocephalus. James MO, et al. **Chem Biol Interact** 1981 Aug; 36(2):229-48

Qualitative and quantitative studies of methylphenobarbital metabolism in man. Hooper WD, et al. **Drug Metab Dispos** 1981 Jul-Aug; 9(4):381-5

The liver-protective enzymes against reduced forms of oxygen in phenobarbital-treated rats. Torres M, et al. **Enzyme** 1981; 26(3):129-35

Effect of diphenylhydantoin and its main hydroxylated metabolite on the pharmacokinetics and the urinary and biliary excretion of phenobarbital and its p-hydroxy metabolite. Sarhan F, et al. **Eur J Drug Metab Pharmacokinet** 1981;6(2):99-108

Neuronal deficits after neonatal exposure to phenobarbital. Yanai J, et al. **Exp Neurol** 1981 Jul;73(1):199-208

Effects of dietary lipid and phenobarbitone on the distribution and concentration of cytochrome P-450 in the liver studied by quantitative cytochemistry. Smith MT, et al. **FEBS Lett** 1981 May 5;127(1):33-6

Determination of partition ratios for allylisopropylacetamide during suicidal processing by a phenobarbital-induced cytochrome P-450 isozyme from rat liver. Loosemore MJ, et al. **J Biol Chem** 1981 Aug 25;256(16):8705-12

Simultaneous assay of methylphenobarbital and phenobarbital in plasma using gas chromatography--mass spectrometry with selected ion monitoring. Hooper WD, et al. **J Chromatogr** 1981 May 8; 223(2):426-31

Detection of phenobarbital in bloodstains, semen, seminal stains, saliva, saliva stains, perspiration stains, and hair. Smith FP, et al. **J Forensic Sci** 1981 Jul;26(3):582-6

Interference of pentobarbitone with the contraction of vascular smooth muscle in goat middle cerebral artery. Marín J, et al. **J Pharm Pharmacol** 1981 Jun;33(6):357-61

Phenobarbitone binding sites in rat brain synaptosomal membranes. Willow M, et al. **Neurosci Lett** 1981 Jul 17;24(3):301-6

Sex-dependent differences in phenobarbitone-induced oestradiol-2-hydroxylase activity in rat liver. Theron CN, et al. **S Afr Med J** 1981 Aug 15;60(7):279-282

A new modified method of measurement of diphenylhydantoin and phenobarbital in serum by high pressure liquid chromatography. Lai ML, et al. **Taiwan I Hsueh Hui Tsa Chih** 1980 Nov;79(11):1002-10

Effects of phenobarbital and beta-naphthoflavone on cerium induced biochemical changes in rat serum. Arvela P, et al. **Toxicol Lett** 1981 Jun-Jul;8(4-5):213-6

Comparative induction of xenobiotic metabolism in rodent kidney, testis and liver by commercial mixtures of polybrominated biphenyls and polychlorinated biphenyls, phenobarbital and 3-methylcholanthrene: absolute and temporal effects. Kluwe WM, et al. **Toxicology** 1981; 20(2-3):259-73

[Lack of effect of phenobarbital on bile flow and Na+,K+-ATPase activity of liver plasma membranes in the hamster (author's transl)] Poupon RE, et al. **Gastroenterol Clin Biol** 1981 Jun-Jul; 5(6-7):604-10 (Eng. Abstr.) **(Fre)**

[Comparative study of the rate of release of phenobarbital from dry galenic forms: the Erweka ZT3 apparatus and the Poole balloon] Duru C, et al. **Pharm Acta Helv** 1981;56(4–5):137–41 (Fre)

[Effect of phenobarbital on self-ratings of healthy subjects in comparison to the objective impairment of their performance] Walther H, et al. **Acta Biol Med Ger** 1980;39(8–9):949–60 (Eng. Abstr.) (Ger)

[Gas chromatographic determination of phenytoin, phenobarbital and primidone: flash-methylation after direct addition of trimethyl-phenyl-ammonium hydroxide to the ethyl acetate extract (author's transl)] Brügmann G. **J Clin Chem Clin Biochem** 1981 May; 19(5):305–6 (Eng. Abstr.) (Ger)

[Effects of phenobarbital on the elimination of valproic acid] Borchert HH, et al. **Pharmazie** 1981 Apr;36(4):298–9 (Ger)

[Interactions between alkaloids of benzyl-isoquinoline structure and barbiturates. Interaction between papaverine hydrochloride an sodium phenobarbitol. I. Study of interactions by physical, chemical and biological methods] Rácz I, et al. **Acta Pharm Hung** 1980 Nov; 50(6):248–56 (Eng. Abstr.) (Hun)

[Interactions between alkaloids of benzyl-isoquinoline structure and barbiturates. Interaction between papaverine hydrochloride and sodium phenobarbitol. II. Pharmacotechnological possibilities of preventing incompatibility] Rácz I, et al. **Acta Pharm Hung** 1980 Nov; 50(6):257–62 (Eng. Abstr.) (Hun)

[Rapid determination, using HPLC, of sodium phenobarbital and its degradation products in syrup] Bennati E, et al. **Boll Chim Farm** 1981 Mar;120(3):172–8 (Eng. Abstr.) (Ita)

[Increase in the number of repeating sequences of DNA in transcriptionally active sites of rat genome induced by cortisol and phenobarbital] Dudareva NA, et al. **Biokhimiia** 1981 Jul; 46(7):1258–66 (Eng. Abstr.) (Rus)

[Possible role of nucleases in the mechanism of the induction effect of phenobarbital] Matiushin AI, et al. **Farmakol Toksikol** 1981 Mar–Apr; 44(2):208–10 (Eng. Abstr.) (Rus)

[Age and the effects of barbiturates on rat liver microsome oxidative enzymes] Paramonova GI. **Farmakol Toksikol** 1981 Jan–Feb; 44(1):98–101 (Eng. Abstr.) (Rus)

[Effect of the long-term administration of testosterone on induction of cytochrome P-450 in female rat live tissue using phenobarbital] Chistiakov VV, et al. **Vopr Med Khim** 1981 May–Jun;27(3):340–2 (Eng. Abstr.) (Rus)

PHENOTHIAZINE TRANQUILIZERS

Gas—liquid chromatographic determination of pipotiazine in plasma of psychiatric patients. Cooper SF, et al. **J Chromatogr** 1981 Feb 13; 222(2):291–6

Clinical blood chemistry values and long acting phenothiazines. Schneider SJ, et al. **Pharmacopsychiatria** 1981 May;14(3):107–14

PHENOTHIAZINES

Determination of promethazine and other phenothiazine compounds by liquid chromatography wih electrochemical detection. Wallace JE, et al. **Anal Chem** 1981 Jun;53(7):960–2

A comparison of the in vivo metabolism of phenothiazine and promazine in the neonatal guinea pig. Mitchell SC, et al. **Biol Neonate** 1981; 39(5–6):285–9

Thionins: plant peptides that modify membrane permeability in cultured mammalian cells. Carrasco L, et al. **Eur J Biochem** 1981 May; 116(1):185–9

Photodecomposition of some substituted phenothiazines. Sharples D. **J Pharm Pharmacol** 1981 Apr;33(4):242–3

The correlation between drug binding to the human erythrocyte and its hemolytic activity. Horie T, et al. **J Pharmacobiodyn** 1981 Feb; 4(2):116–22

Inhibition by phenothiazine antipsychotic drugs of calcium-dependent phosphorylation of cerebral cortex proteins regulated by phospholipid or calmodulin. Wrenn RW, et al. **Life Sci** 1981 Aug 17;29(7):725–33

Influence of UV rays on Feulgen-type staining with azure A-SO2 prepared with normal hydrochloric acid and sodium thiosulphate. Dutt MK. **Microsc Acta** 1981 Jul;84(4):339–44

The influence of psychotropic drugs on the phosphodiesterase activity in the rat brain meninges. Janiec W, et al. **Pol J Pharmacol Pharm** 1980 May–Jun;32(3):297–303

[Electrochemical behavior of phenothiazine in 90% dimethylsulfoxyde–10% water. Analytical application (author's transl)] Livertoux MH, et al. **Ann Pharm Fr** 1980;38(6):513–20 (Eng. Abstr.) (Fre)

[Romanowsky dyes and romanowsky-Giemsa effect. 1. Azure B, purity and content of dye samples, association (author's transl)] Zipfel E, et al. **Histochemistry** 1981;72(2):279–90 (Eng. Abstr.) (Ger)

[Formation of precipitate in an injection solution containing a phenothiazine derivative and novamidazophene] Takács M, et al. **Acta Pharm Hung** 1981 Mar;51(2):55–60 (Eng. Abstr.) (Hun)

[Mutagenicity tests on mequitazine (author's transl)] Sono A, et al. **J Toxicol Sci** 1981 May;6(2):123–8 (Eng. Abstr.) (Jpn)

[Effect of nonachlazine on the calcium mechanism of regulating coronary artery tone] Shishkin SB, et al. **Farmakol Toksikol** 1981 Mar–Apr; 44(2):184–7 (Eng. Abstr.) (Rus)

[Protection of myocardial mitochondria from penetration by calcium ions using isoquinoline and phenothiazine derivatives] Urakov AL, et al. **Farmakol Toksikol** 1981 Jan–Feb;44(1):60–2 (Eng. Abstr.) (Rus)

PHENOXYBENZAMINE

Specific antibodies against the irreversible alpha-adrenergic antagonist, phenoxybenzamine. Goodhardt M, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1685–92

Effects of methysergide or phenoxybenzamine on the renal and cardiovascular responses to endotoxin in rats. Keeler R. **Circ Shock** 1981;8(3):361–8

The effect of phenoxybenzamine on the gastrin response to glycine stimulation. Loh B. **Gastroenterol Jpn** 1981;16(3):205–12

Effects of prazosin and phenoxybenzamine on alpha- and beta-receptor-mediated responses in intestinal resistance and capacitance vessels. Patel P, et al. **J Cardiovasc Pharmacol** 1981 Sep–Oct;3(5):1050–9

Influence of propranolol, phenoxybenzamine of phentolamine in the in vivo nocturnal rise of pineal melatonin levels in the Syrian hamster. Lipton JS, et al. **Life Sci** 1981 May 21;28(21):2377–82

[Phenoxybenzamine in prostatic pathology. 300 cases (author's transl)] Lardennois B, et al. **J Urol (Paris)** 1981;87(4):243–8 (Eng. Abstr.) (Fre)

[Alkylation of ganglionic cholinergic receptors with haloalkyl amines] Blazsó G, et al. **Acta Pharm Hung** 1980 May;50(3):137–44 (Eng. Abstr.) (Hun)

[Effect of phenoxybenzamine on the adrenergic neurone blocking action of guanethidine in isolated guinea pig vas deferens (author's transl)] Kontani H. **Yakugaku Zasshi** 1980 Dec;100(12):1247–51 (Eng. Abstr.) (Jpn)

PHENYLALANINE

Dextro-phenylalanine as inhibitor of the noradrenaline release from the isolated rat hypothalamus. Pardal JF, et al. **Acta Neurol Latinoam** 1979; 25(3–4):235–48

Blood-brain transport of tryptophan and phenylalanine: effect of portacaval shunt in dogs. Huet PM, et al. **Am J Physiol** 1981 Aug; 241(2):G163–9

Dynamics of amino acid side chains in membrane proteins by high field solid state deuterium nuclear magnetic resonance spectroscopy. Phenylalanine, tyrosine, and tryptophan. Kinsey RA, et al. **J Biol Chem** 1981 Sep 10;256(17):9028–36

Analysis of some tryptophan and phenylalanine metabolites in urine by a straight-phase high-performance liquid chromatographic technique. Ghebregzabher M, et al. **J Chromatogr** 1981 Feb 13;222(2):191–201

Potential thyroliberin affinity labels. 1. Chloroacetyl-substituted phenylalanylpyrrolidines. Goebel RJ, et al. **J Med Chem** 1981 Apr; 24(4):366–70

Dietary phenylalanine and tyrosine interrelationships in the Sprague-Dawley rat. Elkin RG, et al. **Proc Soc Exp Biol Med** 1981 Jul;167(3):310–7

[Influence of supplementary tyrosine or phenylalanine on bacterial growth and pigmentation of 'Pseudomonas aeruginosa' (author's transl)] Labeyrie S, et al. **Ann Microbiol (Paris)** 1981 Jan–Feb; 132A(1):31–40 (Eng. Abstr.) (Fre)

PHENYLBUTYRATES

Studies of possible bovine urinary excretion and rumen decomposition of fenvalerate insecticide and metabolite. Wszolek PC, et al. **Bull Environ Contam Toxicol** 1981 Feb;26(2):262–6

Enzymatic synthesis of the coenzyme A ester of o-succinylbenzoic acid, an intermediate in menaquinone (vitamin K2) biosynthesis. Heide L, et al. **FEBS Lett** 1981 Jun 15;128(2):201–4

Preliminary human pharmacology studies on the inhibition of platelet aggregation by indobufen (K 3920). Pogliani E, et al. **Haematologica (Pavia)** 1981 Apr;66(2):160–70

Determination of fenvalerate, a synthetic pyrethroid, in grapes, peppers, apples, and cottonseeds by gas-liquid chromatography. Greenberg RS. **J Agric Food Chem** 1981 Jul–Aug;29(4):856–60

Face fly and horn fly reduction on cattle with fenvalerate ear tags. Knapp FW, et al. **J Econ Entomol** 1981 Jun;74(3):295–6

PHENYLPROPANOLAMINE

Sensitive assay for pseudoephedrine and its metabolite, norpseudoephedrine in plasma and urine using gas—liquid chromatography with electron-capture detection. Lo LY, et al. **J Chromatogr** 1981 Feb 13;222(2):297–302

High-pressure liquid chromatographic determination of methscopolamine nitrate, phenylpropanolamine hydrochloride, pyrilamine maleate, and pheniramine maleate in tablets. Heidemann DR. **J Pharm Sci** 1981 Jul; 70(7):820–2

High-pressure liquid chromatographic analysis of phenylpropanolamine in human plasma following derivatization with O-phthalaldehyde.

Mason WD, et al. **J Pharm Sci** 1981 Jun;70(6):707-9

Are your patients speeding? Mack RB. **NC Med J** 1981 Jul;42(7):489

PHENYTOIN

Opposite effects of 5,5-diphenylhydantoin and picrotoxin on GABAergic inhibition in crayfish stretch receptor. Aickin CC, et al. **Adv Biochem Psychopharmacol** 1981;29:301-7

Studies with excitatory amino acid antagonists in rat CNS: 2-amino-5-phosphonovaleric acid, phenytoin, and benzodiazepines. Stone TW. **Adv Biochem Psychopharmacol** 1981;29:223-30

Audit of phenytoin prescribing for outpatients. Curry CE Jr, et al. **Am J Hosp Pharm** 1981 Aug;38(8):1158-60

Phenytoin by volume-control set [letter] Graves DA. **Am J Hosp Pharm** 1981 Aug;38(8):1119, 1121

Generic phenytoin versus dilantin for once-a-day dosing [letter] Tindula RJ. **Am J Hosp Pharm** 1981 Aug;38(8):1114, 1116

Decreased clearance of phenytoin with cimetidine [letter] Algozzine GJ, et al. **Ann Intern Med** 1981 Aug;95(2):244-5

Saliva carbamazepine and phenytoin level monitoring. Rylance GW, et al. **Arch Dis Child** 1981 Aug;56(8):637-40

The effects of phenytoin on in vitro protein synthesis in oral and non-oral tissues of the rat. Kusek JC. **Arch Oral Biol** 1980;25(11-12):745-7

Acetanilide and paracetamol pharmacokinetics before and during phenytoin administration: genetic control of induction? Cunningham JL, et al. **Br J Clin Pharmacol** 1981 Jan;11(6):591-5

Distinction between the effects of barbiturates, benzodiazepines and phenytoin on responses to gamma-aminobutyric acid receptor activation and antagonism by bicuculline and picrotoxin. Simmonds MA. **Br J Pharmacol** 1981 Jul;73(3):739-47

Cimetidine interaction with phenytoin [letter] Neuvonen PJ, et al. **Br Med J [Clin Res]** 1981 Aug 15;283(6289):501

Effects of phenytoin on [3H]diazepam binding in dissociated primary cortical cell culture. Gallager DW, et al. **Brain Res** 1981 Aug 10; 218(1-2):319-30

Calcium uptake mechanisms affected by some convulsant and anticonvulsant drugs. Pincus JH, et al. **Brain Res** 1981 Jul 27; 217(1):119-27

Phenytoin in the treatment of IgA mesengial glomerulonephritis (Berger's disease) [letter] Egido J, et al. **Clin Nephrol** 1981 Mar;15(3):164-5

Isolation of peptides from uremic plasma that inhibit phenytoin binding to normal plasma proteins. Kinniburgh DW, et al. **Clin Pharmacol Ther** 1981 Aug;30(2):276-80

Comment on phenytoin dosage [letter] Knouse BF. **Drug Intell Clin Pharm** 1981 Mar;15(3):215

Elevated serum phenytoin concentrations in a uremic patient when measured by enzyme-multiplied immunoassay. Matzke GR, et al. **Drug Intell Clin Pharm** 1981 May;15(5):386-8

Effect of diphenylhydantoin and its main hydroxylated metabolite on the pharmacokinetics and the urinary and biliary excretion of phenobarbital and its p-hydroxy metabolite. Sarhan F, et al. **Eur J Drug Metab Pharmacokinet** 1981;6(2):99-108

Chronic treatment with phenytoin in rats: effects of peripheral nervous system. Moglia A, et al. **Farmaco [Sci]** 1981 Jun;36(6):419-24

Inhibition of in vitro diphenylhydantoin hydroxylation by different anticonvulsant drug combinations: a kinetic analysis. Patsalos PN, et al. **Gen Pharmacol** 1981;12(1):51-5

A nonmetabolized analogue of phenytoin. Henderson JD, et al. **J Med Chem** 1981 Jul;24(7):843-7

Estimating dosage of phenytoin [letter] Dodson WE, et al. **J Pediatr** 1981 Jul;99(1):169-70

Comparison of anticonvulsant potencies of cyheptamide, carbamazepine, and phenytoin. Jones GL, et al. **J Pharm Sci** 1981 Jun;70(6):618-20

Predicting individual phenytoin dosage. Vozeh S, et al. **J Pharmacokinet Biopharm** 1981 Apr;9(2):131-46

Altered drug binding to serum proteins in pregnant women: therapeutic relevance. Perucca E, et al. **J R Soc Med** 1981 Jun;74(6):422-6

Drug alert: two forms of dilantin. Gever LN. **Nursing (Horsham)** 1981 Sep;11(9):78

Diphenylhydantoin-induced pseudolymphoma syndrome. With severe thrombocytopenia. Cacatian AA, et al. **NY State J Med** 1981 Jun; 81(7):1085-7

Single point estimation of phenytoin dosing requirement. Koup JR, et al. **Res Commun Chem Pathol Pharmacol** 1981 Jan;31(1):3-12

Phenytoin-induced interstitial nephritis. Hoffman EW. **South Med J** 1981 Sep;74(9):1160-1

Phenytoin-dexamethasone interaction: a previously unreported observation. Lawson LA, et al. **Surg Neurol** 1981 Jul;16(1):23-4

A new modified method of measurement of diphenylhydantoin and phenobarbital in serum by high pressure liquid chromatography. Lai ML, et al. **Taiwan I Hsueh Hui Tsa Chih** 1980 Nov;79(11):1002-10

[Gas chromatographic determination of phenytoin, phenobarbital and primidone: flash-methylation after direct addition of trimethyl-phenyl-ammonium hydroxide to the ethyl acetate extract (author's transl)] Brügmann G. **J Clin Chem Clin Biochem** 1981 May; 19(5):305-6 (Eng. Abstr.) (Ger)

[Pharmacological influences on the brain level and transport of GABA. I) Effect of various antipileptic drugs on brain levels of GABA] Varotto M, et al. **Boll Soc Ital Biol Sper** 1981 Apr 30;57(8):904-8 (Eng. Abstr.) (Ita)

[Five autopsied cases of chronic diphenylhydantoin intoxication — with special reference to the distribution of cerebellar degeneration and marked degeneration of nucleus fasciculi dorsalis (author's transl)] Ando S, et al. **Seishin Shinkeigaku Zasshi** 1980;82(7):423-43 (Eng. Abstr.) (Jpn)

[Quantitative measurement of phenytoin and hydroxyphenytoin in human serum by column extraction-high-performance liquid chromatography (author's transl)] Sato A, et al. **Yakugaku Zasshi** 1980 Dec; 100(12):1215-9 (Eng. Abstr.) (Jpn)

PHOBIC DISORDERS

Treatment of spontaneous panic attacks with chlomipramine. Gloger S, et al. **Am J Psychiatry** 1981 Sep;138(9):1215-7

School phobia: a therapeutic trial with clomipramine and short-term outcome. Berney T, et al. **Br J Psychiatry** 1981 Feb;138:110-8

A multicenter controlled trial in phobic-obsessive psychoneurosis. The effect of chlorimipramine and of its combinations with haloperidol and diazepam. Cassano GB, et al. **Prog Neuropsychopharmacol** 1981; 5(2):129-38

Is the isolated animal a possible model for phobia and anxiety? Garattini S, et al. **Prog Neuropsychopharmacol** 1981;5(2):159-65 (56 ref.)

PHYSOSTIGMINE

Physostigmine in amoxapine overdose [letter] Ross SR, et al. **Am J Hosp Pharm** 1981 Aug;38(8):1121-2

Physostigmine and lithium response in the schizophrenias. Edelstein P, et al. **Am J Psychiatry** 1981 Aug;138(8):1078-81

An analysis of the respiratory stimulant effect of physostigmine and neostigmine in the conscious rabbit. Weinstock M, et al. **Clin Exp Pharmacol Physiol** 1981 Mar-Apr;8(2):151-8

[2 patients poisoned with a centrally acting anticholinergic agent] Ruprecht J, et al. **Ned Tijdschr Geneeskd** 1981 Jun 27;125(26):1041-2 (Eng. Abstr.) (Dut)

PILOCARPINE

Regular fetal breathing induced by pilocarpine infusion in the near-term fetal lamb. Brown ER, et al. **J Appl Physiol** 1981 Jun;50(6):1348-52

High-performance liquid chromatographic analysis of pilocarpine hydrochloride, isopilocarpine, pilocarpic acid and isopilocarpic acid in eye-drop preparations. Kennedy JM, et al. **J Chromatogr** 1981 Aug 7;212(3):331-8

[Comparison of bioavailability of pilocarpine] Eyal E, et al. **Harefuah** 1980 Dec 15;99(12):445-7 (Eng. Abstr.) (Heb)

PIPRADROL

The acquisition of responding with conditioned reinforcement: effects of cocaine, (+)-amphetamine and pipradrol. Beninger RJ, et al. **Br J Pharmacol** 1981 Sep;74(1):149-54

PITUITARY HORMONE RELEASING HORMONES

Gonadotrophin release by gonadotrophs incubated with gonadotrophin-releasing hormone is independent of intracellular cAMP accumulation. Benoist L, et al. **Acta Endocrinol (Copenh)** 1981; 97(3):329-37

Immunohistochemical localization of gonadotropin releasing hormone (GnRH) in the bovine hypothalamus and infundibulum. Dees WL, et al. **Anat Rec** 1981 Jul;200(3):281-5

GnRH-receptor interaction. V. Down-regulation of pituitary receptors for GnRH in ovariectomized ewes by infusion of homologous hormone. Nett TM, et al. **Biol Reprod** 1981 Jun;24(5):1145-55

Evolutionary significance of the phylogenetic distribution of the mammalian hypothalamic releasing hormones. Jackson IM. **Fed Proc** 1981 Sep;40(11):2545-52

The metabolic serum clearance of GnRH. Relationship to age, sex and male puberty. Tharandt L, et al. **Horm Metab Res** 1981 May; 13(5):277-82

Hypophysiotropic hormones of the hypothalamus. Negro-Vilar A, et al. **Int Rev Physiol** 1981;24:97-156 (378 ref.)

Repetitive treatment with gonadotrophin releasing factor or a long-acting analogue upon gonadotrophin secretion in the ferret. Gledhill B, et al. **J Endocrinol** 1981 Aug;90(2):275-83

Reversible inhibition of testicular steroidogenesis and spermatogenesis by a potent gonadotropin-releasing hormone agonist in normal men: an approach toward the development of a male contraceptive. Linde R, et al. **N Engl J Med** 1981 Sep 17;305(12):663-7

Estimation of GnRH pulse amplitude during pubertal development. Corley KP, et al. **Pediatr Res** 1981 Feb;15(2):157-62

Characterization of a 41-residue ovine hypothalamic peptide that stimulates secretion of corticotropin and beta-endorphin. Vale W, et al. **Science** 1981 Sep 18;213(4514):1394–7

[Effect of gonadotropin releasing hormone, clomide and L-dopa on the secretion of chorionic gonadotropins, follicle-stimulating hormone and prolactin in the first trimester of uncomplicated pregnancy] Rzempołuch J. **Ginekol Pol** 1981 Jan;52(2):211–4 **(Pol)**

PITUITARY HORMONES

[Clinical implications of present knowledge respecting neuropharmacologic control of antipituitary hormones] Martin-Du Pan R, et al. **Schweiz Med Wochenschr** 1980 Nov 29;110(48):1784–1814 (346 ref.) (Eng. Abstr.) **(Fre)**

[Hypophyseal hormones--neurotransmitters? (editorial)] Korczyn A. **Harefuah** 1980 Dec 15;99(12):441–2 **(Heb)**

[Effects of cerebral, hypothalamic and hypophyseal peptides on the central nervous system] Comaru-Schally AM, et al. **Medicina (B Aires)** 1981; 41(2):244–56 (108 ref.) **(Spa)**

PITUITARY HORMONES, ANTERIOR

Processing, turnover and release of corticotropins, endorphins and melanotropin in the toad pituitary intermediate lobe. Loh YP. **Ciba Found Symp** 1981;(81):55–78

Functions of alpha-melanotropin and other opiomelanocortin peptides in labour, intrauterine growth and brain development. Swaab DF, et al. **Ciba Found Symp** 1981;(81):196–217

Hypophysiotropic hormones of the hypothalamus. Negro-Vilar A, et al. **Int Rev Physiol** 1981;24:97–156 (378 ref.)

[Effects of intrathecal injection of beta-endorphin on endocrine function in man (author's transl)] Yamaya R. **Masui** 1981 May;30(5):445–52 (Eng. Abstr.) **(Jpn)**

PRAZEPAM

[Pharmacokinetics of oral prazepam] Kölle EU. **Fortschr Med** 1981 Jun 11;99(22):874–9 (Eng. Abstr.) **(Ger)**

PROBLEM SOLVING

Brief fasting, stress, and cognition in children. Pollitt E, et al. **Am J Clin Nutr** 1981 Aug;34(8):1526–33

A new approach to the role of noradrenaline in learning: problem-solving in the marmoset after alpha-noradrenergic receptor blockade. Ridley RM, et al. **Pharmacol Biochem Behav** 1981 Jun;14(6):849–55

PROGESTERONE

Effect of 20 alpha-dihydroprogesterone, progesterone, and their 5 alpha-reduced metabolites on serum gonadotropin levels and hypothalamic LHRH content. Gilles PA, et al. **Biol Reprod** 1981 Jun; 24(5):1088–97

Temporal relationship between the abortifacient effects of GnRH antagonists and hormonal secretion. Rivier C, et al. **Biol Reprod** 1981 Jun;24(5):1061–7

Effects of estradiol and progesterone on plasma gonadotropins, prolactin, and LHRH in specific brain areas of ovariectomized rats. Wise PM, et al. **Biol Reprod** 1981 May;24(4):820–30

The effects of stimulation and lesion of raphe nuclei on luteinizing hormone release in estrogen-progesterone-treated ovariectomized rats. Waloch M, et al. **Brain Res** 1981 Aug 3;217(2):305–13

Electrical stimulation of mesencephalic noradrenergic pathway: effects on luteinizing hormone levels in blood of ovariectomized and ovariectomized, steroid-primed rats. Leung PC, et al. **Endocrinology** 1981 Sep;109(3):720–8

Role of ovarian hormones in the long-term control of glucose homeostasis. Interaction with insulin, glucagon and epinephrine. Ahmed-Sorour H, et al. **Horm Res** 1980;13(6):396–403

Binding of steroids by proteins in follicular fluid of the human ovary. Martin B, et al. **J Clin Endocrinol Metab** 1981 Aug;53(2):443–7

Effect of progesterone on lipid metabolism in the intact rat. Shirling D, et al. **J Endocrinol** 1981 Aug;90(2):285–94

Increase in catecholamine-stimulated cyclic AMP and progesterone synthesis in rat granulosa cells during culture. Kliachko S, et al. **Mol Cell Endocrinol** 1981 Jul;23(1):23–32

[Contraceptive activity and mechanism of action of combinations of 6-methyl-substituted D'6-pentaranes and mestranol] Korkhov VV, et al. **Farmakol Toksikol** 1981 Jan–Feb;44(1):95–8 (Eng. Abstr.) **(Rus)**

PROLACTIN

Effect of short-term bromocriptine treatment on amniotic fluid prolactin concentration in the first half of pregnancy. Lehtovirta P, et al. **Acta Endocrinol (Copenh)** 1981 Aug;97(4):559–61

Effect of electroconvulsive treatment on brain monoamine content, pituitary-adrenal function and plasma prolactin. Arató M, et al. **Acta Physiol Acad Sci Hung** 1980;56(2):163–71

Prolactin secretion in anorexia nervosa. Caufriez A, et al. **Acta Psychiatr Belg** 1980 Jul–Aug;80(4):546–50

TSH, HGH, HPr, and cortisol response to TRH in depressed patients. Ramseier F, et al. **Acta Psychiatr Belg** 1980 Jul–Aug;80(4):399–409

Prolactin and psychiatry. Meltzer HY. **Am J Psychiatry** 1981 Sep; 138(9):1203–6

Daytime variation in serum prolactin level in patients receiving oral and depot antipsychotic medication. Goode DJ, et al. **Biol Psychiatry** 1981 Jul;16(7):653–62

Direct effects of gonadotropin releasing hormone and its antagonist upon ovarian functions stimulated by FSH, prolactin, ans LH. Jones PB, et al. **Biol Reprod** 1981 May;24(4):747–59

Temporal relationship between the abortifacient effects of GnRH antagonists and hormonal secretion. Rivier C, et al. **Biol Reprod** 1981 Jun;24(5):1061–7

Site of action of prolactin in the suppression of gonadotropin secretion during lactation in the rat: effect on pituitary responsiveness to LHRH. Smith MS. **Biol Reprod** 1981 Jun;24(5):967–76

Effects of ageing and gonadal steroid hormones on prolactin concentrations in the anterior pituitary of the chicken. Kono T, et al. **Br Poult Sci** 1980 Nov;21(6):431–6

Lack of a relationship between concentrations of plasma luteinising hormone, thyroxine and prolactin at nine week's of age and subsequent egg production in the domestic hen. Sharp PJ, et al. **Br Poult Sci** 1981 Jan;22(1):53–8

The direct effect of reserpine in vitro on prolactin release from rat anterior pituitary glands. Login IS, et al. **Brain Res** 1981 Jan 5;204(1):79–85

Marked and selective suppression of prolactin secretion after interruption of neural connections of the medial basal hypothalamus of the rat. Mioduszewski R, et al. **Brain Res** 1981 Jul 6;216(1):35–44

Monosodium glutamate: acute and chronic effects on rhythmic growth hormone and prolactin secretion, and somatostatin in the undisturbed male rat. Terry LC, et al. **Brain Res** 1981 Jul 27;217(1):129–42

Prolactin pulsatility in patients with gonadal dysfunction. Moult PJ, et al. **Clin Endocrinol (Oxf)** 1981 Apr;14(4):387–94

Inhibiting effect of atropine on prolactin blood levels after stimulation with TRH. Bizzarro A, et al. **Clin Exp Obstet Gynecol** 1980; 7(2):108–11

Promethazine and diazepam potantiate the haloperidol induced prolactin responses. Arató M. **Commun Psychopharmacol** 1980;4(4):317–22

Delta 9-tetrahydrocannabinol suppression of prolactin secretion in the rat: lack of direct pituitary effect. Hughes CL Jr, et al. **Endocrinology** 1981 Sep;109(3):876–80

Induction and maintenance of gonadotropin and lactogen receptors in hypoprolactinemic rats. Huhtaniemi IT, et al. **Endocrinology** 1981 Aug; 109(2):483–90

Dopaminergic and serotonergic involvement in opiate-induced prolactin release in monkeys. Wehrenberg WB, et al. **Endocrinology** 1981 Aug; 109(2):544–7

Effects of lisuride and bromocriptine on inhibition of lactation and on serum prolactin levels: comparative double-blind study. Venturini PL, et al. **Eur J Obstet Gynaecol Reprod Biol** 1981 May;11(6):395–400

Endogenous hyperprolactinaemia enhances amphetamine- and apomorphine-induced stereotypy. Drago F, et al. **Eur J Pharmacol** 1981 Jun 19;72(2–3):249–53

Pharmacological studies with several analogs of mazindol: correlation between effects on dopamine uptake and various in vivo responses. Heikkila RE, et al. **Eur J Pharmacol** 1981 May 8;71(2–3):277–86

The effects of histidyl-proline-diketopiperazine, a metabolite of TRH, on prolactin release by the rat pituitary gland in vitro. Lamberts SW, et al. **Eur J Pharmacol** 1981 May 8;71(2–3):337–41

Contractile effect of prolactin on guinea pig isolated ileum. Pillai NP, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):11–6

Differences in negative and positive feedback of gonadal steroids on release of gonadotropins and prolactin in young and old rats. Meites J, et al. **Exp Brain Res** 1981;Suppl 3:151–7

Regulation of prolactin secretion at the pituitary level. Ruberg M, et al. **Exp Brain Res** 1981;Suppl 3:182–99 (62 ref.)

Pituitary response to luteinizing hormone-releasing hormone during haloperidol-induced hyperprolactinemia. Del Carmen Díaz M, et al. **Fertil Steril** 1981 Jun;35(6):626–8

Prolactin and the small intestine. Effect of hyperprolactinaemia on mucosal structure in the rat. Muller E, et al. **Gut** 1981 Jul; 22(7):558–65

Novel multialveolar epithelial structures from rabbit mammary gland that synthesize milk specific fatty acids in response to prolactin. Carrington CA, et al. **In Vitro** 1981 May;17(5):363–8

Prolactin in maintenance of the corpus luteum of early pseudopregnancy in the golden hamster. Harris KH, et al. **J Endocrinol** 1981 Aug; 90(2):145–50

2-hydroxyoestradiol inhibits prolactin release from the superfused rat pituitary gland. Linton EA, et al. **J Endocrinol** 1981 Sep; 90(3):315–22

Role of serotonin in the regulation of growth hormone and prolactin secretion in the domestic fowl. Rabii J, et al. **J Endocrinol** 1981 Sep; 90(3):355–8

Dissociation in the regulation of luteinizing hormone and follicle-stimulating hormone in a hyperprolactinaemic rat model: interrelationships between gonadotrophin and prolactin control. Tresguerres JA, et al. **J Endocrinol** 1981 Jul;90(1):41-51

The failure of prolactin to enhance the inhibitory effect of oestradiol-17 beta on LH synthesis and release in ewes. Wright PJ, et al. **J Reprod Fertil** 1981 Jul;62(2):537-42

Prolactin and LH release in response to LH-RH and TRH in ewes during dioestrus, pregnancy and post partum. Wright PJ, et al. **J Reprod Fertil** 1981 Jul;62(2):447-53

In vivo studies on prolactin function in the female rat: divergent effects of treatment with bromergocryptine and antisera to rat prolactin. Kofler R, et al. **J Reprod Immunol** 1981 Sep;3(4):219-25

Treatment of hyperprolactinaemia with pergolide mesylate: acute effects and preliminary evaluation of long-term treatment. Franks S, et al. **Lancet** 1981 Sep 26;2(8248):659-61

Neuroendocrine effects of D,L-propranolol [letter] Malas KL, et al. **Lancet** 1981 Aug 22;2(8243):424

Functional and anatomical segregation of hypothalamic opiate receptors involved in prolactin and growth hormone secretion in cynomolgus monkeys. Belchetz PE. **Life Sci** 1981 Jun 29;28(26):2961-71

During one year's neuroleptic treatment in rats striatal dopamine receptor blockade decreases but serum prolactin levels remain elevated. Dyer RG, et al. **Life Sci** 1981 Jan 12;28(2):167-74

Pharmacological difference of L-dopa, apomorphine, and bromocriptine against metoclopramide. Fang VS. **Life Sci** 1981 May 11; 28(19):2143-9

Effect of 3-PPP, a putative dopamine autoreceptor agonist, on rat serum prolactin levels. Meltzer HY, et al. **Life Sci** 1981 Jul 6;29(1):99-105

Effect of estradiol benzoate and clomiphene on tyrosine hydroxylase activity and on luteinizing hormone and prolactin levels in ovariectomized rats. Tobias H, et al. **Life Sci** 1981 Aug 17; 29(7):711-6

Hyperprolactinemia in chronic renal failure: impaired responsiveness to stimulation and suppression. Normalization after transplantation. Peces R, et al. **Nephron** 1981;28(1):11-6

Stimulation of prolactin secretion in rhesus monkeys by vasoactive intestinal polypeptide. Frawley LS, et al. **Neuroendocrinology** 1981 Aug; 33(2):79-83

Modulation by dopamine antagonists of DNA synthesis in the pituitary gland of the male rat. Jacobi JM, et al. **Neuroendocrinology** 1981 Aug; 33(2):97-100

Hyperprolactinemia counteracts the testosterone-induced inhibition of the preoptic area dopamine turnover. Kalra PS, et al. **Neuroendocrinology** 1981 Aug;33(2):118-22

Effect of lergotrile mesylate and methysergide on morphine induced increase in prolactin release. Ratner A, et al. **Proc West Pharmacol Soc** 1981;24:335-9

The prolactin response in patients receiving neuroleptic therapy. The effect of fluphenazine decanoate. Dotti A, et al. **Prog Neuropsychopharmacol** 1981;5(1):69-77

The prolactin-stimulating potency of reserpine in man. Asnis GM, et al. **Psychiatry Res** 1981 Aug;5(1):39-45

Effect of intramuscular chlorpromazine on serum prolactin levels in schizophrenic patients and normal controls. Meltzer HY, et al. **Psychiatry Res** 1981 Aug;5(1):95-105

The posterior pituitary: regulation of anterior pituitary prolactin secretion. Peters LL, et al. **Science** 1981 Aug 7;213(4508):659-61

[Hyperprolactinemia and primary amenorrhea] Christensen JB. **Ugeskr Laeger** 1981 Apr 6;143(15):933-4 (Eng. Abstr.) **(Dan)**

[Charges in the gonadotrophins, in the prolactin and in the sexual steroid levels throughout the normal menstrual cycle (author's transl)] Buvat J, et al. **J Gynecol Obstet Biol Reprod (Paris)** 1981;10(2):99-108 (Eng. Abstr.) **(Fre)**

[Bromocriptine in the treatment of normal prolactinemic anovulation] Messalli E, et al. **Riv Ital Ginecol** 1980;59(2-3):111-8 **(Ita)**

[Our experience in the inhibition of lactation (Controlled clinical study with bromocriptine, methergoline and pyridoxine)] Vecchione A, et al. **Riv Ital Ginecol** 1980;59(2-3):311-9 (Eng. Abstr.) **(Ita)**

[Effect of gonadotropin releasing hormone, clomide and L-dopa on the secretion of chorionic gonadotropins, follicle-stimulating hormone and prolactin in the first trimester of uncomplicated pregnancy] Rzempołuch J. **Ginekol Pol** 1981 Jan;52(2):211-4 **(Pol)**

PROMAZINE

A comparison of the in vivo metabolism of phenothiazine and promazine in the neonatal guinea pig. Mitchell SC, et al. **Biol Neonate** 1981; 39(5-6):285-9

PROMETHAZINE

Determination of promethazine and other phenothiazine compounds by liquid chromatography wih electrochemical detection. Wallace JE, et al. **Anal Chem** 1981 Jun;53(7):960-2

Interactions of carbon tetrachloride and promethazine in the rat—II. Elimination of carbon tetrachloride and chloroform in expired air as indications of their metabolism in the intact animal. Reddrop CJ, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1449-55

Interactions of carbon tetrachloride and promethazine in the rat—I. Effects of promethazine on the concentrations of carbon tetrachloride in blood and liver, and on the production of chloroform. Reddrop CJ, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1443-7

Promethazine and diazepam potantiate the haloperidol induced prolactin responses. Arató M. **Commun Psychopharmacol** 1980;4(4):317-22

[Protection of myocardial mitochondria from penetration by calcium ions using isoquinoline and phenothiazine derivatives] Urakov AL, et al. **Farmakol Toksikol** 1981 Jan-Feb;44(1):60-2 (Eng. Abstr.) **(Rus)**

PROPANEDIOLS

Acute and chronic propylene glycol dinitrate exposure in the monkey. Mattsson JL, et al. **Aviat Space Environ Med** 1981 Jun;52(6):340-5

Hemoperfusion for detoxification of mercury. A model:treatment of severe mercury poisoning by encapsulated chelating spheres, Part I. Margel S, et al. **Biomater Med Devices Artif Organs** 1981;9(2):107-25

Intramuscular injections of 1,2-propanediol can stimulate rumen papillar development of milk-fed kids. Hamada T, et al. **Experientia** 1981 Jun; 37(6):579-80

PROPRANOLOL

Effect of inotropic interventions on rate of change of ventricular diastolic dimensions. Sabbah HN, et al. **Am J Physiol** 1981 Sep; 241(3):H376-80

Questioning a contraindication of propranolol [letter] Gitlin M. **Am J Psychiatry** 1981 Sep;138(9):1261-2

Effect of propranolol on circulatory responses to induction of diazepam-nitrous oxide anesthesia and to endotracheal intubation. McCammon RL, et al. **Anesth Analg (Cleve)** 1981 Aug;60(8):579-83

Propranolol and retroperitoneal fibrosis [letter] Pierce JR Jr, et al. **Ann Intern Med** 1981 Aug;95(2):244

Effect of isoproterenol and propranolol on the mast cell degranulation and on the passive cutaneous anaphylaxis in mice. Małolepszy J, et al. **Arch Immunol Ther Exp (Warsz)** 1980;28(6):873-8

Influence of propranolol and acebutolol on isoprenaline-induced changes in heart rate and peripheral blood flow in man. Mougeot G, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):116-25

Interesting uses of beta blockers (2): propranolol in schizophrenia. Chiu E. **Aust Fam Physician** 1981 May;10(5):376-9, 381-2

Effects of d- and l-propranolol on the responsiveness of human fibroblasts to choleragen and prostaglandin E1. Moss J, et al. **Biochem Pharmacol** 1981 Jun 1;30(11):1263-9

Propranolol, alprenolol and oxprenolol metabolism in the dog. Identification of N-methylated metabolites. Walle UK, et al. **Biomed Mass Spectrom** 1981 Feb;8(2):78-84

Bioavailability of propranolol and bendrofluazide formulations. McAinsh J, et al. **Biopharm Drug Dispos** 1981 Apr-Jun;2(2):167-75

Effect of metoclopramide on the bioavailability of long-acting propranolol. Charles BG, et al. **Br J Clin Pharmacol** 1981 May; 11(5):517-8

A comparison of the effects of propranolol and oxprenolol on forearm blood flow and skin temperature. Vandenburg MJ, et al. **Br J Clin Pharmacol** 1981 May;11(5):485-90

Influence of cimetidine on pharmacokinetics of propranolol [letter] Bauman JH. **Br Med J [Clin Res]** 1981 Jul 18;283(6285):232

Influence of cimetidine on pharmacokinetics of propranolol [letter] Kitis G. **Br Med J [Clin Res]** 1981 Jul 25;283(6286):309

Effects of indomethacin, renal denervation, and propranolol on plasma renin activity in conscious dogs with chronic thoracic caval constriction. Echtenkamp SF, et al. **Circ Res** 1981 Aug;49(2):492-500

Beneficial effects of adding propranolol to multidose potassium cardioplegia. Kanter KR, et al. **Circulation** 1981 Aug; 64(2 Pt 2):84-90

No stereoselective first-pass hepatic extraction of propranolol. Jackman GP, et al. **Clin Pharmacol Ther** 1981 Sep;30(3):291-6

Systemic and forearm haemodynamic and metabolic effects of racemic propranolol or D-propranolol in healthy subjects. Hartling OJ, et al. **Clin Sci** 1981 Jun;60(6):675-9

Effect of beta-adrenoceptor blockade on exercise performance and metabolism. Lundborg P, et al. **Clin Sci** 1981 Sep;61(3):299-305

Possible toxic interaction of propranolol and narcotic analgesics [letter] Davis WM, et al. **Drug Intell Clin Pharm** 1981 Apr;15(4):290-300

Retroperitoneal fibrosis after treatment with propranolol [letter] Henri L, et al. **Drug Intell Clin Pharm** 1981 Sep;15(9):696

Propranolol and thyroxine metabolism [letter] Nester TJ. **Drug Intell Clin Pharm** 1981 Feb;15(2):131-2

A comparison of circulatory responsiveness following the sudden withdrawal from atenolol and propranolol. Schwartz J, et al. **Eur Heart J** 1981 Feb;2(1):31-9

Physiological evidence (hypothermia) for central effects of beta-blocker agents. Ben-Uriah Y, et al. **Int J Neurosci** 1981;14(1-2):41-6

Effects of concentration and steric configuration of propranolol on AV conduction and ventricular repolarization in the dog. Brorson L, et al. **J Cardiovasc Pharmacol** 1981 Jul-Aug;3(4):692-703

Interaction in healthy volunteers between prenalterol, a selective beta 1-adrenoceptor agonist, and metoprolol or propranolol. Rönn O, et al. **J Cardiovasc Pharmacol** 1981 May-Jun;3(3):477-84

Myocardial sensitivity to isoproterenol following abrupt propranolol withdrawal in conscious dogs. Webb JG, et al. **J Cardiovasc Pharmacol** 1981 May-Jun;3(3):622-35

Comparison of the inotropic and chronotropic effects of metoprolol and propranolol. Conrad KA. **J Clin Pharmacol** 1981 May-Jun; 21(5-6):213-8

Interaction between aminophylline and beta adrenergic blockers 'propranolol' & 'practolol' on the myocardium and tracheal spirals in experimental animals. el-Gawhary NE, et al. **J Egypt Med Assoc** 1979; 62(1-2):171-83

Avoidance of first pass elimination of propranolol after rectal administration to rats. de Boer AG, et al. **J Pharm Pharmacol** 1981 Jan;33(1):50-1

Interaction of propranolol hydrochloride with montmorillonite. Sánchez Martin MJ, et al. **J Pharm Pharmacol** 1981 Jun;33(6):408-10

High-performance liquid chromatographic determination of propranolol and 4-hydroxypropranolol in plasma. Rosseel MT, et al. **J Pharm Sci** 1981 Jun;70(6):688-9

Nonlinear first-pass metabolism of propranolol in the rat. Suzuki T, et al. **J Pharmacobiodyn** 1981 Feb;4(2):131-41

The inhibitory effect of propranolol pretreatment on its own metabolism in the rat. Schneck DW, et al. **J Pharmacol Exp Ther** 1981 Sep; 218(3):575-81

Propranolol and epinephrine [letter] Stotter ML. **JAMA** 1981 Oct 16; 246(16):1772

Interaction of cimetidine with metoprolol, propranolol, or atenolol [letter] Kirch W, et al. **Lancet** 1981 Sep 5;2(8245):531-2

Propranolol, exercise, and arterial plasma potassium [letter] Lim M, et al. **Lancet** 1981 Sep 12;2(8246):591

Neuroendocrine effects of D,L-propranolol [letter] Malas KL, et al. **Lancet** 1981 Aug 22;2(8243):424

Changes in plasma concentrations of acebutolol, propranolol and indomethacin during physical exercise. Henry JA, et al. **Life Sci** 1981 Apr 27;28(17):1925-9

Influence of propranolol, phenoxybenzamine of phentolamine in the in vivo nocturnal rise of pineal melatonin levels in the Syrian hamster. Lipton JS, et al. **Life Sci** 1981 May 21;28(21):2377-82

Augmentation of thoracic duct lymph flow induced by adrenaline in the rabbits treated previously with propranolol. Toyosawa K, et al. **Nippon Seirigaku Zasshi** 1981;43(2):44-5

In vitro detection of possible in vivo drug interactions. Part 1. The effect of hydrochlorothiazide and frusemide on the in vitro absorption characteristics of propranolol hydrochloride. Anber SA, et al. **Pharmazie** 1981 Jun;36(6):425-7

In vitro detection of possible in vivo drug interactions. Part 2: A study of the effect of hydrochlorothiazide and frusemide on the partition coefficient and solubility characteristics of propranolol hydrochloride. Al-Janabi II, et al. **Pharmazie** 1981;36(7):485-8

Arterial and venous blood sampling in pharmacokinetic studies: propranolol in rabbits and dogs. Lam G, et al. **Res Commun Chem Pathol Pharmacol** 1981 Jul;33(1):33-48

Aromatic hydroxylation of propranolol. Stereochemical aspects of the formation of 4'-hydroxypropranolol in the rat. Powell ML, et al. **Res Commun Chem Pathol Pharmacol** 1980 Dec;30(3):387-400

Cerebroventricular propranolol elevates cerebrospinal fluid norepinephrine and lowers blood pressure. Tackett RL, et al. **Science** 1981 Aug 21;213(4510):911-3

Direct determination of propranolol in serum or plasma by fluoroimmunoassay. Al-Hakiem MH, et al. **Ther Drug Monit** 1981; 3(2):159-65

[Effect of propranolol and pindolol on carotid reflexes induced by lobeline] Silva Carvalho L, et al. **C R Trav Lab Carlsberg** 1981; 175(3):416-9 (Eng. Abstr.) **(Fre)**

[A modified fluorimetric method for the determination of propranolol in human plasma] Migulla H, et al. **Pharmazie** 1981 Jun;36(6):443-4 **(Ger)**

[Effect of portasystemic anastomoses in childhood on propranolol pharmacokinetics] Cario WR, et al. **Schweiz Med Wochenschr** 1981 Jul 18;111(29):1088-93 (Eng. Abstr.) **(Ger)**

[Effect of propranolol, nifedipine and aminophylline on ST and T changes in spontaneous cardiac rhythm in patients with artificial pacemaker] Swiatecka G. **Kardiol Pol** 1981;24(5):343-8 (Eng. Abstr.) **(Pol)**

PROSTAGLANDINS

Effects of vasoactive and inflammatory agents on cyclic AMP levels in W138 fibroblasts, endothelial and vascular smooth muscle cells in culture. Ager A, et al. **Agents Actions** 1980 Dec;10(6):569-72

Bradykinin effects on adrenergic transmission in the canine kidney: relation to prostaglandins. Sušić H, et al. **Am J Physiol** 1981 Sep; 241(3):R146-51

Differential effects of itanoxone--a new hypolipidemic and hypouricemic drug--on platelet and vascular prostaglandin generation in rats. Livio M, et al. **Atherosclerosis** 1981 Jul;39(4):469-77

Evidence against an obligatory role for catecholamine release or prostacyclin synthesis in the effects of relaxin on the rat uterus. Sanborn BM, et al. **Biol Reprod** 1981 Jun;24(5):987-92

Prostacyclin and beta-adrenergic catecholamines inhibit arachidonate release and PGI2 synthesis by vascular endothelium. Adler B, et al. **Blood** 1981 Sep;58(3):514-7

Differential effects of prostaglandins on canine intrapulmonary arteries and veins. Altura BM, et al. **Br J Pharmacol** 1981 Aug;73(4):819-27

Inhibition of anterior pituitary prostaglandin-stimulated adenylyl cyclase activity by somatostatin. Rouleau D, et al. **Can J Biochem** 1981 Apr; 59(4):307-10

Effects of various prostanoids on thyrotropin secretion by superfused anterior pituitary cells. Wright KC, et al. **Endocrinology** 1981 Aug; 109(2):637-43

Effect of prostaglandins D2, E2 and F2alpha on catecholamine release from slices of rat and rabbit brain. Reimann W, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):421-7

Stimulation of cyclic AMP production by vasoactive agents in cultured bovine aortic and pulmonary artery endothelial cells. Makarski JS. **In Vitro** 1981 May;17(5):450-8

A simultaneous radioimmunoassay for aldosterone and its precursors: human plasma levels following the inhibition of converting enzyme, before and after blockade of prostaglandin biosynthesis. Witzgall H, et al. **J Clin Chem Clin Biochem** 1981 Jun;19(6):387-94

Prostacyclin and prostaglandin E2 effects on adrenergic transmission in the kidney of anesthetized dog. Sušić H, et al. **J Pharmacol Exp Ther** 1981 Sep;218(3):588-92

Effects of C-terminal octapeptide of cholecystokinin and prostaglandins on adrenergic functions in the guinea-pig gallbladder and sphincter of Oddi. Nakata K, et al. **Jpn J Pharmacol** 1981 Feb;31(1):77-83

Renal kinin-prostaglandin relationship: implications for renal function. Nasjletti A, et al. **Kidney Int** 1981 Jun;19(6):860-8 (73 ref.)

Prostacyclin-induced hypothermia: involvement of central histamine H2-receptors. Kandasamy SB, et al. **Life Sci** 1981 Jun 1; 28(22):2553-60

Interrelationships among prostaglandins and vasoactive substances. Nasjletti A, et al. **Med Clin North Am** 1981 Jul;65(4):881-9 (60 ref.)

The role of prostaglandins in the alpha- and beta-adrenoceptor mediated renin release response to graded renal nerve stimulation. Kopp U, et al. **Pflugers Arch** 1981 Jul;391(1):1-8

Central effects of prostaglandin D2. Brus R, et al. **Pol J Pharmacol Pharm** 1980;32(5):681-4

Relative contracting and relaxing potencies of a series of prostaglandins on isolated canine mesenteric artery strips. Hatano Y, et al. **Prostaglandins** 1981 Apr;21(4):515-29

Low dose aspirin, platelet function and prostaglandin synthesis: influence of epinephrine and alpha adrenergic blockade. Rao GH, et al. **Prostaglandins Med** 1981 May;6(5):485-94

Stimulated platelet aggregation, thromboxane B2 formation and platelet sensitivity to prostacyclin - a critical evaluation. Siess W, et al. **Thromb Haemost** 1981 Jun 30;45(3):204-7

[Prostaglandins and the nervous system (review of the literature)] Muratov VD, et al. **Farmakol Toksikol** 1981 Jan-Feb;44(1):121-8 (117 ref.) **(Rus)**

PSYCHIATRY

The psychiatrist's perspective--two images of the patient. Leibow D. **Ann NY Acad Sci** 1981;368:123-7

A prospective study of 60 consecutive psychiatric consultations in a family medicine clinic. Katon W, et al. **J Fam Pract** 1981 Jul;13(1):47-56

PSYCHOLOGICAL TESTS

[Effectiveness of drug testing with the help of psychometric methods. Possibilities and problems] Oswald WD. **Med Welt** 1981 Aug 21; 32(34):1225-31 **(Ger)**

PSYCHOPHARMACOLOGY

The role of information exchange in psychopharmacology. Vartanian FE. **Prog Neuropsychopharmacol** 1981;5(2):201-3

Psychopharmacotherapy: from the 1950s to the 1980s. Pomara N, et al. **Psychosomatics** 1981 Jun;22(6):526-30

IInd Czechoslovakian Symposium of Psychopharmacology, Smolenice, 28th-30th September 1977. **Agressologie** 1979;20(D):235-318 **(Mul)**

PSYCHOPHYSIOLOGIC DISORDERS

[Depression, somatization, suicide. Part 2: Masked depression, suicide] Hertrich O. **Fortschr Med** 1981 Jul 2;99(25):973-7 **(Ger)**

PSYCHOSES, SUBSTANCE-INDUCED

Anticholinergic psychosis: differential diagnosis and management. Hall RC, et al. **Psychosomatics** 1981 Jul;22(7):581-3, 587

PSYCHOTHERAPY

Effects of althesin in psychotherapy of schizophrenics. Preliminary report. Ladisich W. **Acta Psychiatr Belg** 1980 Jul-Aug;80(4):445-51

Pharmacotherapy as an intervention during the stages of psychotherapy. Beitman BD. **Am J Psychother** 1981 Apr;35(2):206-14

Differential therapeutics: a guide to treatment selection. Frances A, et al. **Hosp Community Psychiatry** 1981 Aug;32(8):537-46

Differential effects of cognitive therapy and pharmacotherapy on depressive symptoms. Rush AJ, et al. **J Affective Disord** 1981 Sep; 3(3):221-9

[Theoretical assessment and personal experience with the combination of psychotropic drugs and psychotherapy] Seidler C. **Z Arztl Fortbild (Jena)** 1981 May 1;75(9):412-5 (Ger)

PSYCHOTHERAPY, GROUP

Group therapy in the management of manic-depressive illness. Volkmar FR, et al. **Am J Psychother** 1981 Apr;35(2):226-34

Enhancing medication compliance in coffee groups. Olarte SW, et al. **Hosp Community Psychiatry** 1981 Jun;32(6):417-9

[Psychiatric practice as it appears in the Balint group] Guyotat J. **Schweiz Arch Neurol Neurochir Psychiatr** 1981;128(2):251-61 (Eng. Abstr.) (Fre)

PSYCHOTIC DISORDERS

Covert values in the treatment of psychosis. Halleck SL. **Am J Psychother** 1981 Apr;35(2):173-86

Daytime variation in serum prolactin level in patients receiving oral and depot antipsychotic medication. Goode DJ, et al. **Biol Psychiatry** 1981 Jul;16(7):653-62

Dopamine hypothesis in acute psychosis [letter] Marsden CD. **Br J Psychiatry** 1981 Mar;138:269-70

Rapid parenteral treatment of acute psychosis. Menuck M, et al. **Compr Psychiatry** 1981 Jul-Aug;22(4):351-61 (69 ref.)

Using drug holidays for chronic outpatients. Sharer DR, et al. **Hosp Community Psychiatry** 1981 Jun;32(6):420-1

Use of psychotropic drugs in psychiatric conditions; psychiatric problems - recent advances in diagnosis and treatment. Tupin JP. **Proc Annu Meet Med Sect Am Counc Life Insur** 1980;5:67-85

Substance P-like immunoreactivity in plasma of psychotic patients and effects of neuroleptics and electroconvulsive therapy. Kaiya H, et al. **Psychiatry Res** 1981 Aug;5(1):11-21

[Clinical experience with the preparation lithium carbonicum retard in psychiatry (author's transl)] Zapletálek M, et al. **Cesk Psychiatr** 1981 Apr;77(2):110-5 (Eng. Abstr.) (Cze)

[Relationship between pharmacotherapy and psychotherapy of psychoses] Molcan J, et al. **Agressologie** 1979;20(D):283-5 (Eng. Abstr.) (Ger)

[Unsolved problems in the indications for lithium prophylaxis in affective and schizoaffective disorders] Angst J. **Bibl Psychiatr** 1981; (161):32-44 (Eng. Abstr.) (Ger)

[Lithium prophylaxis in schizoaffective psychoses] Lenz G, et al. **Bibl Psychiatr** 1981;(161):45-57 (54 ref.) (Ger)

[High-dosed neuroleptic therapy] Platz T, et al. **Pharmacopsychiatria** 1981 Jul;14(4):141-7 (82 ref.) (Eng. Abstr.) (Ger)

[Comparative characteristics of the preventive properties of short-acting and delayed-action lithium carbonate in endogenous affective psychoses] Panteleeva GP, et al. **Zh Nevropatol Psikhiatr** 1981; 81(3):406-12 (Eng. Abstr.) (Rus)

QUINIDINE

Pharmacokinetic analysis of intravenously and orally administered quinidine in horses. McGuirk SM, et al. **Am J Vet Res** 1981 Jun; 42(6):938-42

Comments on: 'anticholinergic effects of disopyramide and quinidine on guinea pig myocardium--mediation by direct muscarinic receptor blockade' [letter] Benfey BG. **Circ Res** 1981 Sep;49(3):821

Enterogastric cycle and intoxication with hydroquinidine: a case report. Lesne M, et al. **Clin Toxicol** 1981 Jun;18(6):659-62

Clinical aspects of the digoxin-quinidine interaction. Pedersen KE. **Dan Med Bull** 1981 Aug;28(3):128-31

The specificity of the extraction fluorescence assay for serum or plasma quinidine. Greenblatt DJ, et al. **J Clin Pharmacol** 1981 Aug-Sep; 21(8-9):333-6 (17 ref.)

Effects of quinidine, procainamide and disopyramide on automaticity and cyclic AMP content of guinea-pig atria. Mirro MJ. **J Mol Cell Cardiol** 1981 Jul;13(7):641-53

Comparative uptake of quinine and quinidine in rat lung. Minchin RF, et al. **J Pharm Pharmacol** 1981 Jul;33(7):464-6

Assignment of conformation and configuration to potassium permanganate oxidation products of quinidine. Yanuka Y, et al. **J Pharm Sci** 1981 Jun;70(6):675-9

Tissue binding sites involved in quinidine-cardiac glycoside interactions. Kim DH, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):357-62

[Absolute bioavailability of an aqueous solution of quinidine administered orally to the rat and evaluation of the enterohepatic cycle (author's transl)] Koskas JP, et al. **J Pharm Belg** 1981 May-Jun;36(3):193-9 (Eng. Abstr.) (Fre)

[Application of a micromethod for sampling and for the specific quantitative evaluation of quinidine. I. Pharmacokinetic study after intravenous administration in the rat (author's transl)] Koskas JP, et al. **J Pharm Belg** 1981 May-Jun;36(3):187-92 (Eng. Abstr.) (Fre)

[Quinidine increases digoxin levels] Doering W, et al. **Med Klin** 1981 Jul 3;76(14):395-8 (Ger)

[Fluorometric determination of the concentration of quinidine in blood] Gnilitskaia VB, et al. **Lab Delo** 1981;(8):511 (Rus)

RECEPTORS, ADRENERGIC

Dopaminergic and adrenergic effects on plasma LH levels in rats with hypothalamic islands. van Dieten JA, et al. **Acta Endocrinol (Copenh)** 1981;97(3):289-96

Central action of adrenaline. Jagiello-Wójtowicz E. **Acta Physiol Pol** 1981 Mar-Apr;32(2):169-80

A cellular activator of catecholamine-sensitive adenylate cyclase in rat reticulocytes and erythrocytes: changes during reticulocyte development and effects on the beta receptor. Shane E, et al. **Arch Biochem Biophys** 1981 May;208(2):418-25

Differences in the effects of acetylcholine on the vas deferens from normal and castrated rats. A participation of adrenergic mechanisms. Agostini M del C, et al. **Arch Int Pharmacodyn Ther** 1981 Apr;250(2):212-20

Effects of dopamine and its antagonist domperidone cannot be explained by an effect on alpha 1-adrenergic receptors. Schuurkes JA, et al. **Arch Int Pharmacodyn Ther** 1981 Apr;250(2):324-7

Different sedimentation properties of agonist- and antagonist-labelled platelet alpha 2 adrenergic receptors. Michel T, et al. **Biochem Biophys Res Commun** 1981 Jun 16;100(3):1131-6

Effects on fluorine analogs of norepinephrine on stimulation of cyclic adenosine 3',5'-monophosphate and binding to beta-adrenergic receptors in intact pinealocytes. Auerbach DA, et al. **Biochem Pharmacol** 1981 May 15;30(10):1085-9

No evidence for reverse trans-synaptic regulation of neuronal uptake by beta-adrenoceptors in kitten atria. Cornish EJ, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1439-42

Presynaptic alpha-adrenergic mediation of self-stimulation in locus coeruleus in rats treated neonatally with 6-hydroxydopamine. Umemoto M, et al. **Brain Res** 1981 Aug 24;219(1):107-19

Relative location of alpha- and beta-adrenoceptors to sites of release of sympathetic transmitter in the rabbit facial vein. Winquist RJ, et al. **Circ Res** 1981 Aug;49(2):486-92

Cardiac beta-adrenoreceptors in the thyroxine-treated dog. Ho K, et al. **Clin Exp Pharmacol Physiol** 1981 Mar-Apr;8(2):183-7

Alpha-adrenergic stimulation by clonidine increases plasma concentrations of immunoreactive beta-endorphin in rats. Pettibone DJ, et al. **Endocrinology** 1981 Sep;109(3):798-802

Interaction of desipramine and amitriptyline with adrenergic mechanisms in the human iris in vivo. Szabadi E, et al. **Eur J Clin Pharmacol** 1981; 19(6):403-8

Lack of modulation by presynaptic alpha 2-adrenoceptors of adrenergic transmitters release evoked by activation of 5-hydroxytryptamine and nicotine receptors. Carr SR, et al. **Eur J Pharmacol** 1981 Jun 10; 72(1):27-34

Relation between brain catecholamine receptors and dopaminergic stereotypy in rat strains. Helmeste DM, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):465-70

Down-regulation of beta-adrenergic activity in astroglia by chronic treatment with an antidepressant drug. Hertz L, et al. **Eur J Pharmacol** 1981 Jun 19;72(2-3):267-8

An interaction between prejunctional alpha-adrenoceptors and prejunctional beta-adrenoceptors. Majewski H, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):493-8

Involvement of noradrenergic and dopaminergic neurons in shock-induced jumping in rats. Nishikawa T, et al. **Eur J Pharmacol** 1981 May 22;71(4):429-36

Pre- and postsynaptic alpha-adrenoceptor antagonism by neuroleptics in vivo. Petersen EN. **Eur J Pharmacol** 1981 Feb 19;69(4):399-405

Physiological evidence (hypothermia) for central effects of beta-blocker agents. Ben-Uriah Y, et al. **Int J Neurosci** 1981;14(1-2):41-6

Effects of prazosin and phenoxybenzamine on alpha- and beta-receptor-mediated responses in intestinal resistance and capacitance vessels. Patel P, et al. **J Cardiovasc Pharmacol** 1981 Sep-Oct;3(5):1050-9

Mechanism of the age-related decrease of epinephrine-stimulated lipolysis in isolated rat adipocytes: beta-adrenergic receptor binding, adenylate cyclase activity, and cyclic AMP accumulation. Dax EM, et al. **J Lipid Res** 1981 Aug;22(6):934-43

Age-related changes in the central catecholaminergic function and its interaction with methamphetamine during postnatal life in the rat. Nomura Y, et al. **J Pharm Pharmacol** 1981 Apr;33(4):264-6

Cholinergic and alpha adrenergic augmentation of histamine-induced contraction of canine airway smooth muscle. Leff AR, et al. **J Pharmacol Exp Ther** 1981 Sep;218(3):582-7

Site(s) and ionic basis of alpha-autoinhibition and facilitation of [3H]noradrenaline secretion in guinea-pig vas deferens. Alberts P, et al. **J Physiol (Lond)** 1981 Mar;312:297-334

Localization of specialized noradrenaline receptors at neuromuscular junctions on arterioles of the guinea-pig. Hirst GD, et al. **J Physiol (Lond)** 1981;313:343-50

Pre- and postsynaptic adrenergic activation by norepinephrine reuptake inhibitors in the field-stimulated rat vas deferens. Lotti VJ, et al. **Life Sci** 1981 Aug 10;29(6):633-9

Adrenaline activation of phosphofructokinase in rat heart mediated by alpha-receptor mechanism independent of cyclic AMP. Clark MG, et al. **Nature** 1981 Jul 30;292(5822):461-3

Conditions required for the inhibitory feedback loop in noradrenergic transmission. Story DF, et al. **Nature** 1981 Sep 3;293(5827):62-5

Stimulation of prostaglandin E2-synthesis by noradrenaline in primary cell cultures from rabbit splenic pulpa is mediated by atypical alpha-adrenoceptors. Brückner-Schmidt R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb;316(1):1-7

Two different biophases for adrenaline released by electrical stimulation or tyramine from the sympathetic nerve endings of the dog saphenous vein. Guimarães S, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jun;316(3):200-4

The noradrenaline receptor coupled adenylate cyclase system in brain. Lack of modification by changes in the availability of serotonin. Mishra R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jun; 316(3):218-24

Norepinephrine uptake in aging adrenergic nerve terminals. Hoffman DW, et al. **Neurobiol Aging** 1980 Summer;1(1):65-8

Evidence for a growth hormone releasing factor mediating alpha-adrenergic influence on growth hormone secretion in the rat. Eden S, et al. **Neuroendocrinology** 1981 Jul;33(1):24-7

Importance of norepinephrine alpha 2-receptor activation for morphine-induced rat growth hormone secretion. Eriksson E, et al. **Neuroendocrinology** 1981 Aug;33(2):91-6

Adaptive changes in catecholamine receptors in the central nervous system. Reisine T. **Neuroscience** 1981;6(8):1471-502

The role of prostaglandins in the alpha- and beta-adrenoceptor mediated renin release response to graded renal nerve stimulation. Kopp U, et al. **Pflugers Arch** 1981 Jul;391(1):1-8

The central noradrenergic transmission and the locus coeruleus: a review of the data, and their implications for neurotransmission and neuromodulation. van Dongen PA. **Prog Neurobiol** 1981; 16(2):117-43 (303 ref.)

[The effects of Citrus aurantium and its active ingredient N-methyltyramine on the cardiovascular receptors (author's transl)] Chen X, et al. **Yao Hsueh Hsueh Pao** 1981 Apr;16(4):253-9 (Eng. Abstr.) **(Chi)**

RECEPTORS, CHOLINERGIC

Interaction of imipramine with the ionic channel of the acetylcholine receptor of motor endplate and electric organ. Eldefrawi ME, et al. **Biochem Pharmacol** 1981 Jun 1;30(11):1391-4

Mechanism of inactivation (desensitization) of acetylcholine receptor. Investigations by fast reaction techniques with membrane vesicles. Aoshima H, et al. **Biochemistry** 1981 Jun 9;20(12):3467-74

Muscarinic acetylcholine receptors regulation and protein phosphorylation in primary cultures of rat cerebellum. Burgoyne RD, et al. **Brain Res** 1981 Aug;254(1):55-63

Cholinergic receptor interactions and their effects on long-term memory processing. Flood JF, et al. **Brain Res** 1981 Jun 29;215(1-2):177-85

8-Br-cyclic GMP mimics activation of muscarinic autoreceptor and inhibits acetylcholine release from rat hippocampal slices. Nordström O, et al. **Brain Res** 1981 Jun 1;213(2):467-71

Comments on: 'anticholinergic effects of disopyramide and quinidine on guinea pig myocardium—mediation by direct muscarinic receptor blockade' [letter] Benfey BG. **Circ Res** 1981 Sep;49(3):821

Lack of modulation by presynaptic alpha 2-adrenoceptors of adrenergic transmitters release evoked by activation of 5-hydroxytryptamine and nicotine receptors. Carr SR, et al. **Eur J Pharmacol** 1981 Jun 10; 72(1):27-34

The loss of muscarinic acetylcholine receptors in synaptic membranes under phosphorylating conditions is dependent on calmodulin. Burgoyne RD. **FEBS Lett** 1981 May 5;127(1):144-8

Slow cholinergic and peptidergic transmission in sympathetic ganglia. Brown DA, et al. **Fed Proc** 1981 Sep;40(11):2625-30

Acetylcholine receptor kinetics at slow fiber neuromuscular junctions. Dionne VE. **Fed Proc** 1981 Sep;40(11):2614-7

Muscarinic receptors in chromaffin cell cultures mediate enhanced phospholipid labeling but not catecholamine secretion. Fisher SK, et al. **J Neurochem** 1981 Aug;37(2):491-7

Desensitization of the muscarinic acetylcholine receptor of atrium in bullfrogs. Tokimasa T, et al. **Jpn J Physiol** 1981;31(1):83-97

Striatal muscarinic receptors: regulation by dopaminergic agonists. Ehlert FJ, et al. **Life Sci** 1981 May 21;28(21):2441-8

Brain cholinergic dysfunction and memory in aged rats. Lippa AS, et al. **Neurobiol Aging** 1980 Summer;1(1):13-9

Cholinergic actions of false neurotransmitters: acetylpyrrolidinecholine. Buccafusco JJ, et al. **Neurosci Lett** 1981 May 29;23(3):319-24

Muscarinic cholinergic influences on ACTH and beta-endorphin release mechanisms in human subjects. Risch SC, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:95-7

Acetylcholine-induced cation translocation across cell membranes and inactivation of the acetylcholine receptor: chemical kinetic measurements in the millisecond time region. Cash DJ, et al. **Proc Natl Acad Sci USA** 1981 Jun;78(6):3318-22

Ultraviolet light-induced labeling by noncompetitive blockers of the acetylcholine receptor from Torpedo marmorata. Oswald R, et al. **Proc Natl Acad Sci USA** 1981 Jun;78(6):3925-9

Dopaminergic regulation of muscarinic receptor binding in the corpus striatum. Ehlert FJ, et al. **Proc West Pharmacol Soc** 1981;24:93-5

Chronic phencyclidine induced changes in rat central cholinergic receptor regulation. Ward DP, et al. **Proc West Pharmacol Soc** 1981;24:3-4

Failure of muscarinic blockade to antagonize analepsis induced by thyrotropin-releasing hormone and MK-771 in the rat. Santori EM, et al. **Psychopharmacology (Berlin)** 1981;74(1):13-6

[Alkylation of ganglionic cholinergic receptors with haloalkyl amines] Blazsó G, et al. **Acta Pharm Hung** 1980 May;50(3):137-44 (Eng. Abstr.) **(Hun)**

[Regulation of the functioning of molluscan neuron cholinoreceptors by succinate and noradrenaline] Andreev AA, et al. **Dokl Akad Nauk SSSR** 1981;258(6):1466-9 **(Rus)**

RECEPTORS, DOPAMINE

Kainic acid induced lesion of ventral tegmental area: locomotor effect of apomorphine. Morgenstern R. **Acta Biol Med Ger** 1980; 39(8-9):911-5

Dopaminergic and adrenergic effects on plasma LH levels in rats with hypothalamic islands. van Dieten JA, et al. **Acta Endocrinol (Copenh)** 1981;97(3):289-96

Modifications of the dopaminergic receptors sensitivity and learning of normoxic or hypobaric hypoxic rats. Saligaut C, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):80-7

Dopamine receptor alterations with aging in mouse and rat corpus striatum. Marquis JK, et al. **Biochem Pharmacol** 1981 Jul 1; 30(13):1876-8

Disrupted latent inhibition in the rat with chronic amphetamine or haloperidol-induced supersensitivity: relationship to schizophrenic attention disorder. Solomon PR, et al. **Biol Psychiatry** 1981 Jun; 16(6):519-37

Evidence for an inhibitory presynaptic component of neuroleptic drug action. de Belleroche JS, et al. **Br J Pharmacol** 1981 Mar; 72(3):427-33

Puberty of female rats may in part be explained by decreased hypothalamic dopamine receptor sensitivity. Lamberts R, et al. **Brain Res** 1981 [illegible] 29;215(1-2):375-81

Chronic lead treatment induces in rat a specific and differential effect on dopamine receptors in different brain areas. Lucchi L, et al. **Brain Res** 1981 Jun 1;213(2):397-404

[3H]Spiperone binding sites in brain: autoradiographic localization of multiple receptors. Palacios JM, et al. **Brain Res** 1981 Jun 1; 213(2):277-89

Differential functional ontogeny of dopamine presynaptic receptor regulation. Shalaby IA, et al. **Brain Res** 1981 Jun;227(3):434-9

Kainic acid lesions dissociate [3H] spiperone and [3H]cis-flupenthixol binding sites in rat striatum. Cross AJ, et al. **Eur J Pharmacol** 1981 May 8;71(2-3):327-32

Relation between brain catecholamine receptors and dopaminergic stereotypy in rat strains. Helmeste DM, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):465-70

Characteristics of the dopamine receptors in the rabbit isolate splenic artery. Hilditch A, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):287-96

Involvement of dopamine in circling responses to muscimol depends on intranigral site of injection. Kilpatrick IC, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):407-19

Presence of a particular subpopulation of dopamine receptors within the septal nuclei: a behavioural study on cats. Megens AA, et al. **Eur J Pharmacol** 1981 May 8;71(2-3):247-58

Involvement of noradrenergic and dopaminergic neurons in shock-induced jumping in rats. Nishikawa T, et al. **Eur J Pharmacol** 1981 May 22;71(4):429-36

REM sleep deprivation induces subsensitivity of dopamine receptors mediating sedation in rats. Serra G, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):131-5

Synthesis and pharmacological evaluation of sulfonium analogues of dopamine: nonclassical dopamine agonists. Anderson K, et al. **J Med Chem** 1981 Jun;24(6):683-7

Monophenolic 2-(dipropylamino)indans and related compounds: central dopamine-receptor stimulating activity. Hacksell U, et al. **J Med Chem** 1981 Apr;24(4):429-34

Characterization of normal and supersensitive dopamine receptors: effects of ergot drugs and neuropeptides. Fuxe K, et al. **J Neural Transm** 1981; 51(1-2):3-37

The effects of lisuride and some other dopaminergic agonists on receptor binding in human brain. Reynolds GP, et al. **J Neural Transm** 1981; 51(1-2):107-11

Relevance of the rodent area postrema to dopamine-dependent behavioural effects. Costall B, et al. **J Pharm Pharmacol** 1981 Apr; 33(4):257-9

Effect of GABAergic drugs on dopamine catabolism in the nigrostriatal and mesolimbic dopaminergic pathways of the rat. Gundlach AL, et al. **J Pharm Pharmacol** 1981 Jan;33(1):41-3

During one year's neuroleptic treatment in rats striatal dopamine receptor blockade decreases but serum prolactin levels remain elevated. Dyer RG, et al. **Life Sci** 1981 Jan 12;28(2):167-74

Development of dopamine receptor denervation supersensitivity in the neostriatum of the senescent rat. Joseph JA, et al. **Life Sci** 1981 Aug 10;29(6):575-84

Effect of 3-PPP, a putative dopamine autoreceptor agonist, on rat serum prolactin levels. Meltzer HY, et al. **Life Sci** 1981 Jul 6;29(1):99-105

Demonstration of specific vascular dopamine receptors mediating vasodilation on the isolated rabbit mesenteric artery. Brodde OE, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb;316(1):24-30

Dopamine receptor mediated inhibition by pergolide of electrically-evoked 3H-dopamine release from striatal slices of cat and rat: slight effect of ascorbate. Lehmann J, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Aug;317(1):31-5

Effect of combined treatment with dopaminergic and GABA-ergic drugs on the threshold for maximal electroconvulsions in mice. Czuczwar SJ. **Pol J Pharmacol Pharm** 1981 Jan-Feb;33(1):25-35

Dopamine receptor binding in inbred mice: strain differences in mesolimbic and nigrostriatal dopamine binding sites. Boehme RE, et al. **Proc Natl Acad Sci USA** 1981 May;78(5):3255-9

3H-Flupenthixol binding in post-mortem brains of schizophrenics: evidence for a selective increase in dopamine D2 receptors. Cross AJ, et al. **Psychopharmacology (Berlin)** 1981;74(2):122-4

Effect of chronic amphetamine administration on central dopaminergic mechanisms in the vervet. Owen F, et al. **Psychopharmacology (Berlin)** 1981;74(3):213-6

[Interrelationship of the tranquilizers diazepam and lonetil with dopamine mediation in the central nervous system] Ovcharov R, et al. **Eksp Med Morfol** 1981;20(2):88-96 (Eng. Abstr.) **(Bul)**

[Central depletion of transmitters by reserpine and motor behavior in the rat (author's transl)] Funk KF, et al. **Acta Biol Med Ger** 1980; 39(8-9):923-7 (Eng. Abstr.) **(Ger)**

[Role of dopamine receptors in regulating glutamatergic synaptic transmission in the rat neostriatum] Godukhin OV, et al. **Fiziol Zh SSSR** 1981 Mar;67(3):384-9 (Eng. Abstr.) **(Rus)**

RECEPTORS, DRUG

Interaction of depressant, convulsant, and anticonvulsant barbiturates with the [3H]diazepam binding site of the benzodiazepine-GABA-receptor-ionophore complex. Ticku MK. **Biochem Pharmacol** 1981 Jun 15;30(12):1573-9

Stimulation of benzodiazepine binding to rat brain membranes and solubilized receptor complex by avermectin B1a and gamma-aminobutyric acid. Pong SS, et al. **Biochim Biophys Acta** 1981 Aug 6;646(1):143-50

Benzodiazepine and GABA receptors in the rat retina: effect of light and dark adaptation. Biggio G, et al. **Brain Res** 1981 Jul 6; 216(1):210-4

Binding of beta-carboline-3-carboxylic acid ethyl ester to mouse brain benzodiazepine receptors in vivo. Hirsch JD, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):357-60

[3H] Ethyl beta-carboline-3-carboxylate binding to the benzodiazepine receptor is not affected by GABA. Patel J, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):419-20

Action of pyrazolopyridines as modulators of [3H]flunitrazepam binding to the gaba/benzodiazepine receptor complex of the cerebellum. Supavilai P, et al. **Eur J Pharmacol** 1981 Mar 12;70(2):183-93

[3H]Propyl beta-carboline-3-carboxylate as a selective radioligand for the BZ1 benzodiazepine receptor subclass. Braestrup C, et al. **J Neurochem** 1981 Aug;37(2):333-41

Identification and distribution of neuroleptic binding sites in the rat spinal cord. Demenge P, et al. **J Neurochem** 1981 Jul;37(1):53-9

Distribution of specific high-affinity binding sites for [3H]imipramine in human brain. Langer SZ, et al. **J Neurochem** 1981 Aug;37(2):267-71

Benzodiazepine antagonist Ro 15-1788: binding characteristics and interaction with drug-induced changes in dopamine turnover and cerebellar cGMP levels. Möhler H, et al. **J Neurochem** 1981 Sep; 37(3):714-22

GABA-benzodiazepine-barbiturate receptor interactions. Olsen RW. **J Neurochem** 1981 Jul;37(1):1-13 (146 ref.)

Characterization of benzodiazepine and gamma-aminobutyric recognition sites and their endogenous modulators. Massotti M, et al. **J Neurosci** 1981 Apr;1(4):409-18

Reductions in retinal gamma-aminobutyric acid (GABA) content and in [3H]flunitrazepam binding after postnatal monosodium glutamate injections in rats. Regan JW, et al. **J Pharmacol Exp Ther** 1981 Sep; 218(3):791-6

Benzodiazepine receptors are coupled to a subpopulation of gamma-aminobutyric acid (GABA) receptors: evidence from a quantitative autoradiographic study. Unnerstall JR, et al. **J Pharmacol Exp Ther** 1981 Sep;218(3):797-804

Antagonism of benzodiazepine receptors by beta carbolines. O'Brien RA, et al. **Life Sci** 1981 Jul 6;29(1):75-82

Pentobarbital enhances [3H]diazepam binding to soluble receptors at the benzodiazepine--GABA-receptor-ionophore complex. Davis WC, et al. **Neurosci Lett** 1981 May 6;23(2):209-13

Receptor autoradiography with tritium-sensitive film: potential for computerized densitometry. Palacios JM, et al. **Neurosci Lett** 1981 Sep 1;25(2):101-5

Regional specificity of benzodiazepine receptor down-regulation during chronic treatment of rats with flurazepam. Rosenberg HC, et al. **Neurosci Lett** 1981 Jun 12;24(1):49-52

Phenobarbitone binding sites in rat brain synaptosomal membranes. Willow M, et al. **Neurosci Lett** 1981 Jul 17;24(3):301-6

Histidine modification with diethyl pyrocarbonate shows heterogeneity of benzodiazepine receptors. Burch TP, et al. **Proc Natl Acad Sci USA** 1981 Jun;78(6):3945-9

[Pharmacological and toxicological aspects of benzodiazepine compounds (author's transl)] Kapp W. **Anaesth Intensivther Notfallmed** 1981 Jun; 16(3):125-7 (Eng. Abstr.) **(Ger)**

RECEPTORS, ENDORPHIN

Interaction of tritiated beta-endorphin with rat brain membranes. Hammonds RG Jr, et al. **Anal Biochem** 1981 Jun;114(1):75-84

Dual action of meperidine on the frog neuromuscular junction: a prejunctional, opiate receptor-mediated depression of transmitter release and a postjunctional, nonopiate receptor effect on the endplate. Durham HD, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):150-65

Development of acute tolerance during exposure of hippocampal explants to an opioid peptide. Gähwiler BH. **Brain Res** 1981 Jul 27; 217(1):196-200

Functional and anatomical segregation of hypothalamic opiate receptors involved in prolactin and growth hormone secretion in cynomolgus monkeys. Belchetz PE. **Life Sci** 1981 Jun 29;28(26):2961-71

Opioid activities of beta-casomorphins. Brantl V, et al. **Life Sci** 1981 Apr 27;28(17):1903-9

Release of immunoreactive-dynorphin from the isolated guinea-pig small intestine is reduced during peristaltic activity. Kromer W, et al. **Neurosci Lett** 1981 Aug 7;25(1):53-6

Localization and opiate receptor binding of enkephalin, CCK and ACTH/beta-endorphin in the rat central nervous system. Stengaard-Pedersen K, et al. **Peptides (Fayetteville)** 1981; 2 Suppl 1:3-19 (53 ref.)

Relationship between urinary free cortisol and CSF opioid binding activity in depressed patients and normal volunteers. Rubinow DR, et al. **Psychiatry Res** 1981 Aug;5(1):87-93

[Interaction of D-Ala2-[Tyr-3,5-3H]enkephalin(5-D-Leu) with opiate receptors of rat brain] Balashov AM, et al. **Biokhimiia** 1981 Jun; 46(6):1067-72 (Eng. Abstr.) **(Rus)**

[Endogenous opioids in the central nervous system] Hedner T. **Lakartidningen** 1981 Jul 22;78(30-31):2689-93 (Eng. Abstr.) **(Swe)**

RECEPTORS, HORMONE

Potentiation of prostaglandin E2-induced release of LH by the prostaglandin analogue, 7-oxa-13-prostynoic acid. Warberg J. **Acta Endocrinol (Copenh)** 1981;97(3):297-304

Receptor amplifying effect of serotonin and serotonin analogues in a protozoan (Tetrahymena) model system. Csaba G, et al. **Acta Physiol Acad Sci Hung** 1980;56(4):411-6

Long lasting amplification and deformation of thyroid receptors after thyrotropin (TSH) and gonadotropin (GTH) treatment of chickens in the foetal period. Nagy SU, et al. **Acta Physiol Acad Sci Hung** 1980; 56(3):303-7

Dose dependence of the thyrotropin (TSH) receptor damaging effect of gonadotropin in the newborn rats. Nagy SU, et al. **Acta Physiol Acad Sci Hung** 1980;56(4):417-20

Role of GABA-ergic receptors for the synthesis of GABA in different compartments of the rat cerebellum. Carmona E, et al. **Acta Physiol Scand** 1981 May;112(1):109-10

Physiological study of amino acid uptake and receptor desensitization: the GABA system in dorsal root ganglia. Désarménien M, et al. **Adv Biochem Psychopharmacol** 1981;29:309-19

Transport models of the neurotransmitter-receptor interaction. Vieth WR, et al. **Ann NY Acad Sci** 1981;369:99-111

The influence of sodium gamma-hydroxybutyrate on GABA receptors and catecholamine effect potentiation. Kozhechkin SN. **Arch Int Pharmacodyn Ther** 1981 Apr;250(2):242-53

Substance P binds to the formylpeptide chemotaxis receptor on the rabbit neutrophil. Marasco WA, et al. **Biochem Biophys Res Commun** 1981 Apr 30;99(4):1065-72

Interaction of depressant, convulsant, and anticonvulsant barbiturates with the [3H]diazepam binding site of the benzodiazepine-GABA-receptor-ionophore complex. Ticku MK. **Biochem Pharmacol** 1981 Jun 15;30(12):1573-9

Stimulation of benzodiazepine binding to rat brain membranes and solubilized receptor complex by avermectin B1a and gamma-aminobutyric acid. Pong SS, et al. **Biochim Biophys Acta** 1981 Aug 6;646(1):143-50

GnRH-receptor interaction. V. Down-regulation of pituitary receptors for GnRH in ovariectomized ewes by infusion of homologous hormone. Nett TM, et al. **Biol Reprod** 1981 Jun;24(5):1145-55

Distinction between the effects of barbiturates, benzodiazepines and phenytoin on responses to gamma-aminobutyric acid receptor activation and antagonism by bicuculline and picrotoxin. Simmonds MA. **Br J Pharmacol** 1981 Jul;73(3):739-47

Benzodiazepine and GABA receptors in the rat retina: effect of light and dark adaptation. Biggio G, et al. **Brain Res** 1981 Jul 6; 216(1):210-4

Ultrastructure of GABA-neurons in cultures of rat neostriatum. Panula P, et al. **Brain Res** 1981 Aug 24;219(1):202-7

Properties of [3H](3-Me-His2)TRH binding to apparent TRH receptors in the sheep central nervous system. Taylor RL, et al. **Brain Res** 1981 Aug 10;218(1-2):207-17

Benzodiazepine binding and interactions with the GABA receptor complex in living cultures of rat cerebral cortex. White WF, et al. **Brain Res** 1981 Jun 29;215(1-2):162-76

Epidermal growth factor induces rapid tyrosine phosphorylation of proteins in A431 human tumor cells. Hunter T, et al. **Cell** 1981 Jun; 24(3):741-52

Induction and maintenance of gonadotropin and lactogen receptors in hypoprolactinemic rats. Huhtaniemi IT, et al. **Endocrinology** 1981 Aug; 109(2):483-90

In vivo evidence for GABAergic control of serotonin release in the cat substantia nigra. Soubrié P, et al. **Eur J Pharmacol** 1981 Feb 19; 69(4):483-8

Action of pyrazolopyridines as modulators of [3H]flunitrazepam binding to the gaba/benzodiazepine receptor complex of the cerebellum. Supavilai P, et al. **Eur J Pharmacol** 1981 Mar 12;70(2):183-93

Experimental study of hormone receptor development in a unicellular model system. Csaba G, et al. **Exp Cell Biol** 1981;49(3):173-6

Photo-affinity inactivation of gonadotropin releasing hormone receptors. Hazum E. **FEBS Lett** 1981 Jun 1;128(1):111-3

Neurotransmitter receptors: neuroanatomical localization through autoradiography. Murrin LC. **Int Rev Neurobiol** 1981;22:111-71 (379 ref.)

Epimeric cis-decahydroquinoline-5-carboxylic acids: effects on gamma-aminobutyric acid uptake and receptor binding in vitro. Witiak DT, et al. **J Med Chem** 1981 Jul;24(7):788-94

Characterization of the binding of the GABA agonist [3H]piperidine-4-sulphonic acid to bovine brain synaptic membranes. Krogsgaard-Larsen P, et al. **J Neurochem** 1981 Aug;37(2):401-9

Characterization of gamma-aminobutyric acid binding sites on crude synaptic membranes. Kurioka S, et al. **J Neurochem** 1981 Aug; 37(2):283-8

Effects of sodium and bicarbonate ions on gamma-aminobutyric acid receptor binding in synaptic membranes of rat brain. Kurioka S, et al. **J Neurochem** 1981 Aug;37(2):418-21

GABA-benzodiazepine-barbiturate receptor interactions. Olsen RW. **J Neurochem** 1981 Jul;37(1):1-13 (146 ref.)

Characterization of benzodiazepine and gamma-aminobutyric recognition sites and their endogenous modulators. Massotti M, et al. **J Neurosci** 1981 Apr;1(4):409-18

Different efficacies of d- and l-gamma-amino-beta-hydroxybutyric acids in GABA receptor and transport test systems. Roberts E, et al. **J Neurosci** 1981 Feb;1(2):132-40

Lack of effect of benzodiazepines on bicuculline-insensitive GABA-receptors in the field-stimulated guinea-pig vas deferens preparation. Doble A, et al. **J Pharm Pharmacol** 1981 Apr; 33(4):267-8

Binding of luteinizing hormone-releasing hormone analogues to dispersed rat pituitary cells. Meidan R, et al. **Life Sci** 1981 Apr 27; 28(17):1961-7

Somatostatin modulates effects of angiotensin II in adrenal glomerulosa zone. Aguilera G, et al **Nature** 1981 Jul 16;292(5820):262-3

Modulation of platelet shape and membrane receptor binding by Ca2+-calmodulin complex. Kao KJ, et al. **Nature** 1981 Jul 2; 292(5818):82-4

Human transforming growth factors induce tyrosine phosphorylation of EGF receptors. Reynolds FH Jr, et al. **Nature** 1981 Jul 16; 292(5820):259-62

The effects of muscimol and picrotoxin injections into the cat substantia nigra. Wolfarth S, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Aug;317(1):54-60

Endogenous inhibitors of Na+-independent [3H]GABA binding to crude synaptic membranes. Massotti M, et al. **Neurochem Res** 1981 May; 6(5):551-65

Pentobarbital enhances [3H]diazepam binding to soluble receptors at the benzodiazepine--GABA-receptor-ionophore complex. Davis WC, et al. **Neurosci Lett** 1981 May 6;23(2):209-13

GABA receptors distribution in rat substantia nigra. De Montis GM, et al. **Neurosci Lett** 1981 May 29;23(3):257-61

Effect of combined treatment with dopaminergic and GABA-ergic drugs on the threshold for maximal electroconvulsions in mice. Czuczwar SJ. **Pol J Pharmacol Pharm** 1981 Jan-Feb;33(1):25-35

Somatostatin receptors: identification and characterization in rat brain membranes. Srikant CB, et al. **Proc Natl Acad Sci USA** 1981 Jun; 78(6):3930-4

Hindbrain GABA receptors influence parasympathetic outflow to the stomach. Williford DJ, et al. **Science** 1981 Oct 9;214(4517):193-4

RECEPTORS, SEROTONIN

Reactivity of isolated trachea, bronchus and lung strip of cats of carbachol, 5-hydroxytryptamine and histamine: evidence for the existence of methysergide-sensitive receptors. Chand N. **Br J Pharmacol** 1981 Aug; 73(4):853-7

Different hypothalamic receptors mediate 5-hydroxytryptamine- and tryptamine-induced core temperature changes in the rat. Cox B, et al. **Br J Pharmacol** 1981 Mar;72(3):477-82

The maturation of cortical serotonin binding sites. Uphouse LL, et al. **Brain Res** 1981 Jun;227(3):415-7

Supersensitivity of nigral serotonin receptors and rat rotational behaviour. Blackburn TP, et al. **Eur J Pharmacol** 1981 May 8;71(2-3):343-6

Lack of modulation by presynaptic alpha 2-adrenoceptors of adrenergic transmitters release evoked by activation of 5-hydroxytryptamine and nicotine receptors. Carr SR, et al. **Eur J Pharmacol** 1981 Jun 10; 72(1):27-34

Differential effects of electroconvulsive shock and antidepressant drugs on serotonin-2 receptors in rat brain. Kellar KJ, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):515-8

Effects of fluoxetine on a specific serotonergic syndrome in rats. Keshavan HJ, et al. **Indian J Med Res** 1981 Apr;73:653-7

Characterisation of inhibitory 5-hydroxytryptamine receptors that modulate dopamine release in the striatum. Ennis C, et al. **J Neurochem** 1981 Apr;36(4):1515-20

Localisation of tricyclic antidepressant binding sites on serotonin nerve terminals. Sette M, et al. **J Neurochem** 1981 Jul;37(1):40-2

A pre-junctional action of 5-hydroxytryptamine and methysergide on noradrenergic nerves in dog isolated saphenous vein. Watts AD, et al. **J Pharm Pharmacol** 1981 Aug;33(8):515-20

Evidence for 5-HT2 receptors mediating contraction in vascular smooth muscle. Cohen ML, et al. **J Pharmacol Exp Ther** 1981 Aug; 218(2):421-5

5-Hydroxytryptamine-induced hypothermia in rats as an in vivo model for the quantitative study of 5-hydroxytryptamine receptors. Cox B, et al. **J Pharmacol Methods** 1981 Jan;5(1):43-51

Electrophysiological evidence for the existence of separate receptor mechanisms mediating the action of 5-hydroxytryptamine. Berridge MJ. **Mol Cell Endocrinol** 1981 Jul;23(1):91-104

Modulation of affinity of postsynaptic serotonin receptors by antidepressant drugs. Fillion G, et al. **Nature** 1981 Jul 23; 292(5821):349-51

Central action of mepiprazole. Maj J, et al. **Pol J Pharmacol Pharm** 1980 Jul-Aug;32(4):475-84

Effect of chloro-N-desmethyldiazepam on serum and brain tryptophan and serotonin in relation to the activity of central serotonergic neurons. Valzelli L, et al. **Pol J Pharmacol Pharm** 1981 Jan-Feb;33(1):37-42

Uterine serotonin and receptor blockade during estrogen-induced uterine hyperemia. Van Orden DE, et al. **Proc Soc Exp Biol Med** 1981 Sep; 167(4):469-74

Lithium increases serotonin release and decreases serotonin receptors in the hippocampus. Treiser SL, et al. **Science** 1981 Sep 25; 213(4515):1529-31

REFLEX

Arterial baroreceptor reflex function in the conscious rabbit after brainstem lesions coinciding with the A1 group of catecholamine neurons. West MJ, et al. **Circ Res** 1981 Oct;49(4):959-70

Angiotensin and the cardiac baroreflex response to phenylephrine. Lee WB, et al. **Clin Exp Pharmacol Physiol** 1981 Mar-Apr;8(2):109-17

Effects of dopamine on chemoreflexes in breathing. Nishino T, et al. **J Appl Physiol** 1981 Apr;50(4):892-7

The somato-adrenal medullary reflexes in rats. Araki T, et al. **J Auton Nerv Syst** 1981 Apr;3(2-4):161-70

Tonic catecholaminergic inhibition of the spinal somato-sympathetic reflexes originating in the ventrolateral medulla oblongata. Dembowsky K, et al. **J Auton Nerv Syst** 1981 Apr;3(2-4):277-90

Effects of noradrenergic and serotonergic neurons on blood pressure, heart rate and baroreceptor-heart rate reflex of the conscious rabbit. Korner PI, et al. **J Auton Nerv Syst** 1981 Apr;3(2-4):511-23

Interaction between perfusion pressure and sympathetic nerves in renin release by carotid baroreflex in conscious dogs. Gross R, et al. **J Physiol (Lond)** 1981;313:237-50

[Effect of propranolol and pindolol on carotid reflexes induced by lobeline] Silva Carvalho L, et al. **C R Trav Lab Carlsberg** 1981; 175(3):416–9 (Eng. Abstr.) **(Fre)**

[Effect of enkephalins on central processes regulating hemodynamics] Medvedev OS, et al. **Biull Eksp Biol Med** 1981 May;91(5):574–6 (Eng. Abstr.) **(Rus)**

[Changes in lymph flow during reflexes from lymph vessels] Myrzakhanov NM. **Fiziol Zh SSSR** 1981 Mar;67(3):410–3 **(Rus)**

[Effect of drugs potentiating or inhibiting the activity of locus coeruleus neurons on various types of spinal inhibition in the cat] Iakhnitsa IA, et al. **Neirofiziologiia** 1981;13(3):247–58 (Eng. Abstr.) **(Rus)**

REINFORCEMENT (PSYCHOLOGY)

Rewarding effect of noradrenergic stimulation of the amygdala in food deprived rats. Jurkowlaniec E, et al. **Physiol Behav** 1981 Jul; 27(1):27–31

The partial reinforcement extinction effect: influence of chlordiazepoxide in septal lesioned rats. Feldon J, et al. **Psychopharmacology (Berlin)** 1981; 74(3):280–9

REINFORCEMENT SCHEDULE

Drug effects on multiple and alternating mixed-schedule performance. Leander JD. **J Pharmacol Exp Ther** 1981 Sep;218(3):728–33

RESERPINE

Differential effect of REM stimulating and REM inhibiting drugs (reserpine and amitriptylin) on memory. Faber J, et al. **Act Nerv Super (Praha)** 1981 Jun;23(2):169–71

The direct effect of reserpine in vitro on prolactin release from rat anterior pituitary glands. Login IS, et al. **Brain Res** 1981 Jan 5;204(1):79–85

Comparison of reserpine-induced supersensitivity of newborn and adult rabbit ventricular muscles to cardiotonic agents. Park MK, et al. **Dev Pharmacol Ther** 1981;2(4):240–9

Effect of cold, restraint, reserpine, and splanchnicotomy on the ornithine decarboxylase activity of rat adrenal medulla and cortex. Ramirez-Gonzalez D, et al. **Exp Neurol** 1981 Sep;73(3):632–41

Reserpine added to neuroleptic-tricyclic in refractory schizophrenics. Bacher N, et al. **J Clin Psychiatry** 1981 Aug;42(8):326

Differential effects of several dopamine uptake inhibitors and releasing agents on locomotor activity in normal and in reserpinized mice. Heikkila RE. **Life Sci** 1981 Apr 27;28(17):1867–73

Kinetic characteristics of newly synthesized 3H-5-HT in the brain of control and reserpinized mice. Evidence for the heterogeneous distribution of 5-HT in serotoninergic neurons. Morot-Gaudry Y, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jul;316(4):311–6

Agonist selectivity of reserpine induced inotropic supersensitivity. Rodgers RL, et al. **Proc West Pharmacol Soc** 1981;24:233–6

The prolactin-stimulating potency of reserpine in man. Asnis GM, et al. **Psychiatry Res** 1981 Aug;5(1):39–45

Antagonism of reserpine rigidity without inducing sedation. Southwick S, et al. **Psychopharmacology (Berlin)** 1981;74(1):29–32

Effects of reserpine treatment on beta-adrenergic/adenylate cyclase modulate secretion and resynthesis by the rat submandibular gland. Cutler LS, et al. **Virchows Arch [Pathol Anat]** 1981;392(2):185–98

[The non-specific pharmacodynamic action of chronic treatment with reserpine-like neuroadrenergic system antagonist (Raunervil) on the stability of sexual function] Simionescu S, et al. **Physiologie** 1981; 18(2):89–97 **(Fre)**

[Central depletion of transmitters by reserpine and motor behavior in the rat (author's transl)] Funk KF, et al. **Acta Biol Med Ger** 1980; 39(8–9):923–7 (Eng. Abstr.) **(Ger)**

[Supersensitivity by reserpine and means of antagonizing it] Westermann KH. **Acta Biol Med Ger** 1980;39(8–9):941–7 (Eng. Abstr.) **(Ger)**

[Influence of the central dopaminergic system on GABAergic activity of the cerebellum. Preliminary results] Di Giorgio RM, et al. **Acta Neurol [Quad] (Napoli)** 1981;42:302–4 (Eng. Abstr.) **(Ita)**

[On the National Institute of Hygienic Sciences standard (the Japanese Pharmacopoeia standard) 'Reserpine Reference Standard (control 761)' (author's transl)] Ohta M. **Eisei Shikenjo Hokoku** 1980;98:132–3 (Eng. Abstr.) **(Jpn)**

[Neuropharmacological drugs effect on functional activity of rat brain] Dzhaliashvili TA, et al. **Ukr Biokhim Zh** 1981 Mar–Apr; 53(2):109–14 (Eng. Abstr.) **(Rus)**

[Interference of magnesium in reserpine and aminophenazone interaction (author's transl)] Zábojníková M, et al. **Bratisl Lek Listy** 1981; 75(6):677–80 (Eng. Abstr.) **(Slo)**

RUBIDIUM

Somatostatin: mechanism of action in pancreatic islet beta-cells. Pace CS, et al. **Diabetes** 1981 Oct;30(10):836–42

Activation of active Na transport in sheep Purkinje fibres by external K or Rb ions. Glitsch HG, et al. **Pflugers Arch** 1981 Jul; 391(1):28–34

[Changes in the alkaline cation transport across the plasma membrane of CHO-K1 cell lines resistant to ethidium bromide] Marakhova II, et al. **Tsitologiia** 1981 Apr;23(4):410–8 (Eng. Abstr.) **(Rus)**

SCHIZOPHRENIA

Effects of althesin in psychotherapy of schizophrenics. Preliminary report. Ladisich W. **Acta Psychiatr Belg** 1980 Jul–Aug;80(4):445–51

Further clinical experiences with optical isomers of the L and D clorothepin. Náhunek K, et al. **Agressologie** 1979;20(D):275–8

Physostigmine and lithium response in the schizophrenias. Edelstein P, et al. **Am J Psychiatry** 1981 Aug;138(8):1078–81

CSF GABA in normal subjects and patients with depression, schizophrenia, mania, and anorexia nervosa. Gerner RH, et al. **Am J Psychiatry** 1981 Aug;138(8):1098–101

Very high dose loxapine in refractory schizophrenic patients. Lehmann CR, et al. **Am J Psychiatry** 1981 Sep;138(9):1212–4

The effect of pimozide on CSF norepinephrine in schizophrenia. Sternberg DE, et al. **Am J Psychiatry** 1981 Aug;138(8):1045–50

Span of apprehension deficits during the postpsychotic stages of schizophrenia. A replication and extension. Asarnow RF, et al. **Arch Gen Psychiatry** 1981 Sep;38(9):1006–11

Middle molecular weight substances and tryptophan in cerebrospinal fluid of schizophrenic patients. Sperschneider H, et al. **Artif Organs** 1981 May;5(2):177–8

Interesting uses of beta blockers (2): propranolol in schizophrenia. Chia E. **Aust Fam Physician** 1981 May;10(5):376–9, 381–2

Psychopharmacological and social aspects of schizophrenia: recent developments. Paykel ES. **Aust NZ J Psychiatry** 1980 Dec; 14(4):241–7

Neuroleptics decrease blinking in schizophrenic subjects. Karson C, et al. **Biol Psychiatry** 1981 Jul;16(7):679–82

Total and free serum haloperidol levels in schizophrenic patients and the effect of age thioridazine and fatty acid on haloperidol-serum protein binding in vitro. Rowell FJ, et al. **Br J Clin Pharmacol** 1981 Apr; 11(4):377–82

Changes in the hostility of schizophrenic patients during treatment. Tsiantis J, et al. **Br J Med Psychol** 1981 Sep;54(Pt 3):251–8

Positive and negative schizophrenic symptoms and the role of dopamine [letter] Ashcroft GW, et al. **Br J Psychiatry** 1981 Mar;138:268–9

Phenothiazine withdrawal in schizophrenics in a hostel [letter] Mathur S, et al. **Br J Psychiatry** 1981 Mar;138:271–2

Psychophysiological responses of schizophrenic patients to high and low expressed emotion relatives. Sturgeon D, et al. **Br J Psychiatry** 1981 Jan;138:40–5

Fluphenazine resistant psychosis. Brent R, et al. **Can J Psychiatry** 1981 Mar;26(2):118–9

Acutely ill schizophrenic patients treated with loxapine. A clinical study in a community mental health center. Rasul M. **Clin Ther** 1980; 3(4):242–9

Apomorphine in schizophrenia. Hollister LE, et al. **Commun Psychopharmacol** 1980;4(4):277–81

Differential sensitivity to the effects of psychotropic drugs: psychotics vs normals; Asian vs Western populations. Okuma T. **Folia Psychiatr Neurol Jpn** 1981;35(1):79–87

Protein binding of chlorpromazine in cerebrospinal fluid and serum. Alfredsson G, et al. **Int Pharmacopsychiatry** 1980;15(5):261–9

Gas--liquid chromatographic determination of pipotiazine in plasma of psychiatric patients. Cooper SF, et al. **J Chromatogr** 1981 Feb 13; 222(2):291–6

Reserpine added to neuroleptic-tricyclic in refractory schizophrenics. Bacher N, et al. **J Clin Psychiatry** 1981 Aug;42(8):326

Bilateral skin conductance, finger pulse volume, and EEG orienting response to tones of differing intensities in chronic schizophrenics and controls. Bernstein AS, et al. **J Nerv Ment Dis** 1981 Aug; 169(8):513–28

gamma-Aminobutyric acid concentration in cerebrospinal fluid in schizophrenia. McCarthy BW, et al. **J Neurochem** 1981 Apr; 36(4):1406–8

Pindolol in schizophrenia [letter] O'Connor M. **Med J Aust** 1981 Apr 18;1(8):429

Effects of chronic amphetamine treatment on the glutamate concentration in cerebrospinal fluid and brain: implications for a theory of schizophrenia. Kim JS, et al. **Neurosci Lett** 1981 Jun 12;24(1):93–6

A double-blind comparison of bromperidol and haloperidol in newly admitted schizophrenic patients. Brannen JO, et al. **Pharmacopsychiatria** 1981 Jul;14(4):139–40

Gamma-hydroxybutyrate treatment of schizophrenia: a pilot study. Schulz SC, et al. **Pharmacopsychiatria** 1981 Jul;14(4):129–34

A follow-up study of schizophrenic outpatients treated with depot-neuroleptics. Tegeler J, et al. **Prog Neuropsychopharmacol** 1981; 5(1):79–90

Effects of long-term neuroleptic use on brain density. Lyon K, et al. **Psychiatry Res** 1981 Aug;5(1):33–7

Effect of intramuscular chlorpromazine on serum prolactin levels in schizophrenic patients and normal controls. Meltzer HY, et al. **Psychiatry Res** 1981 Aug;5(1):95–105

Acute amphetamine response predicts antidepressant and antipsychotic responses to lithium carbonate in schizophrenic patients. van Kammen DP, et al. **Psychiatry Res** 1981 Jun;4(3):313–25

(Des-Tyr)-gamma-endorphin in the treatment of schizophrenia. Manchanda R, et al. **Psychol Med** 1981 May;11(2):401–4

3H-Flupenthixol binding in post-mortem brains of schizophrenics: evidence for a selective increase in dopamine D2 receptors. Cross AJ, et al. **Psychopharmacology (Berlin)** 1981;74(2):122–4

Information and consent in schizophrenic patients in long-term treatment. Linden M, et al. **Schizophr Bull** 1981;7(3):372–8

[On the question of differences between therapeutic responses after particular neuroleptics in comparison to perphenazine in schizophrenics (author's transl)] Náhunek K, et al. **Cesk Psychiatr** 1981 Feb; 77(1):25–30 (Eng. Abstr.) **(Cze)**

[Flufenazine decanoate in the ambulatory treatment of schizophrenic patients] Populin M, et al. **Minerva Psichiatr** 1981 Apr–Jun; 22(2):85–92 (73 ref.) (Eng. Abstr.) **(Ita)**

[Changes in the levels of adrenergic and serotoninergic indices in patients with depressive states] Misionzhnik EIu, et al. **Zh Nevropatol Psikhiatr** 1981;81(4):543–51 (Eng. Abstr.) **(Rus)**

[Dynamics of the remission of acute schizophrenic episodes during psychopharmacologic treatment] Sverdlov LS. **Zh Nevropatol Psikhiatr** 1981;(5):737–43 (Eng. Abstr.) **(Rus)**

[Treatment of schizophrenic patients with clomacran. A transcultural study (author's transl)] Torres Ruiz A, et al. **Arch Neurobiol (Madr)** 1981 Mar–Apr;44(2):117–24 (Eng. Abstr.) **(Spa)**

SCHIZOPHRENIA, DISORGANIZED

Neuroendocrine function in schizophrenia. Brambilla F. **Acta Psychiatr Belg** 1980 Jul–Aug;80(4):421–35

SELF STIMULATION

The temporal structure of motivation IV: A reexamination of extinction effects in intracranial reward. Katz RJ. **Behav Neural Biol** 1981 Jun; 32(2):191–200

Increase in mesolimbic electrical self-stimulation after chronic haloperidol: reversal by L-DOPA or lithium. Seeger TF, et al. **Brain Res** 1981 Jun 29;215(1–2):404–9

Presynaptic alpha-adrenergic mediation of self-stimulation in locus coeruleus in rats treated neonatally with 6-hydroxydopamine. Umemoto M, et al. **Brain Res** 1981 Aug 24;219(1):107–19

Effects of GABAergic drugs on brain stimulation reward as assessed by a 'threshold' method. Zarevics P, et al. **Brain Res** 1981 Jun 29; 215(1–2):201–9

Post-amphetamine depression of self-stimulation behavior in rats: prophylactic effects of lithium. Predy PA, et al. **Neurosci Lett** 1981 May 29;23(3):343–7

Amphetamine enhancement of reward asymmetry. Glick SD, et al. **Psychopharmacology (Berlin)** 1981;73(4):323–7

Self-stimulation and amphetamine: tolerance to d and l isomers and cross tolerance to cocaine and methylphenidate. Leith NJ, et al. **Psychopharmacology (Berlin)** 1981;74(1):23–8

[Effect of euphorigenic drugs on emotionally-positive brain systems] Zvartau EE, et al. **Zh Vyssh Nerv Deiat** 1981;31(2):308–14 (Eng. Abstr.) **(Rus)**

SEROTONIN

Effect of hypophysectomy and adrenalectomy on 5-hydroxytryptamine uptake by rat hypothalamic synaptosomes and blood platelets. Tukiainen E. **Acta Pharmacol Toxicol (Copenh)** 1981 Feb;48(2):139–44

Characterization of 5-hydroxytryptamine uptake in sliced rat lung. Wikberg JE, et al. **Acta Pharmacol Toxicol (Copenh)** 1981 Feb; 48(2):151–6

Receptor amplifying effect of serotonin and serotonin analogues in a protozoan (Tetrahymena) model system. Csaba G, et al. **Acta Physiol Acad Sci Hung** 1980;56(4):411–6

Effect of cholecystokinin octapeptide sulphate ester on brain monoamines in the rat. Fekete M, et al. **Acta Physiol Acad Sci Hung** 1981; 57(1):37–46

Effects of high oxygen tension on the metabolism of vasoactive hormones in isolated perfused rat lungs. Toivonen H, et al. **Acta Physiol Scand** 1981 Feb;111(2):185–92

Autoradiographic and immunocytochemical evidence for the existence of GABAergic neurons in the nucleus raphe dorsalis--possible existence of neurons containing 5HT and glutamate decarboxylase. Nanopoulos D, et al. **Adv Biochem Psychopharmacol** 1981;29:519–25

Cyclic AMP modulation of a specific ion channel in an identified nerve cell: possible role for protein phosphorylation. Levitan IB, et al. **Adv Cyclic Nucleotide Res** 1981;14:647–53

Electroencephalographic serotonin synchronization: area postrema and solitary tract nucleus. Yamasaki K, et al. **Am J Physiol** 1981 Sep; 241(3):R158–62

Reverse-phase high-performance liquid chromatographic separation and electrochemical detection of norepinephrine, dopamine, serotonin, and related major metabolites. Kempf E, et al. **Anal Biochem** 1981 Apr; 112(2):223–31

Differential interaction of 5-HT with chicken and rat aorta. Laekeman GM, et al. **Arch Int Pharmacodyn Ther** 1981 Apr;250(2):318–20

Strontium ions induce production of thromboxane B2 and secretion of 5-hydroxytryptamine in washed human platelets. Best LC, et al. **Biochem Pharmacol** 1981 Mar 15;30(6):635–7

Effect of neuroleptics on indoleamine-N-methyltransferase activity and brain metabolism of bufotenin. Gomes UC, et al. **Biochem Pharmacol** 1981 Mar 15;30(6):571–5

Inverse relation of substance P-like immunoreactivity in dorsal raphe nucleus to serotonin levels in pons-medulla following administration of cocaine and 5-hydroxytryptophan. Pradhan S, et al. **Biochem Pharmacol** 1981 May 15;30(10):1071–6

Aromatic L-amino acid decarboxylase activity in central and peripheral tissues and serum of rats with L-DOPA and L-5-hydroxytryptophan as substrates. Rahman MK, et al. **Biochem Pharmacol** 1981 Mar 15; 30(6):645–9

Effects of mianserin, desipramine and maprotiline on blood pressure responses evoked by acetylcholine, histamine and 5-hydroxytryptamine in rats. Cavero I, et al. **Br J Pharmacol** 1981 Sep;74(1):143–8

Reactivity of isolated trachea, bronchus and lung strip of cats of carbachol, 5-hydroxytryptamine and histamine: evidence for the existence of methysergide-sensitive receptors. Chand N. **Br J Pharmacol** 1981 Aug; 73(4):853–7

Anomalous compartmentation of 5-hydroxytryptamine in intact human platelets. Costa JL, et al. **Br J Pharmacol** 1981 Mar;72(3):449–59

Different hypothalamic receptors mediate 5-hydroxytryptamine- and tryptamine-induced core temperature changes in the rat. Cox B, et al. **Br J Pharmacol** 1981 Mar;72(3):477–82

Effects of divalent cations on responses of a sympathetic ganglion to 5-hydroxytryptamine and 1,1-dimethyl-4-phenyl piperazinium. Nash HL, et al. **Br J Pharmacol** 1981 Jul;73(3):759–72

The effects of chronic section of dorsal roots on the responsiveness of motoneurones to 5-hydroxytryptamine and a substance P analogue. Roberts MH, et al. **Br J Pharmacol** 1981 Jul;73(3):589–94

Monoamines in affective illness. Is there a place for 5HT? Eccleston D **Br J Psychiatry** 1981 Mar;138:257–8

The art of measuring serotonin uptake in platelets [letter] Lingjaerde O. **Br J Psychiatry** 1981 1 Feb;138:181

Noradrenergic innervation of serotonergic neurons in the dorsal raphe: demonstration by electron microscopic autoradiography. Baraban JM, et al. **Brain Res** 1981 Jan 5;204(1):1–11

Effect of iontophoretically applied 5-hydroxytryptamine on the excitability of single primary afferent C- and A-fibers in the cat spinal cord. Carstens E, et al. **Brain Res** 1981 Sep 7;220(1):151–8

The response of individual sympathetic preganglionic neurones to microelectrophoretically applied endogenous monoamines. Coote JH, et al. **Brain Res** 1981 Jun 29;215(1–2):135–45

5-Hydroxytryptamine reduces substance P responses on dorsal horn interneurones: a possible interaction of neurotransmitters. Davies JE, et al. **Brain Res** 1981 Aug 3;217(2):399–404

Stimulation of the rat dorsal raphe in vivo releases labeled serotonin from the parietal cortex. Fujiwara H, et al. **Brain Res** 1981 Jul 20; 216(2):351–60

In vitro cellular adaptation of serotonergic processes after chronic central phenobarbital administration. Lyness WH, et al. **Brain Res** 1981 Jan 5;204(1):248–52

The cortical projection of the dorsal raphe nucleus: some electrophysiological and pharmacological properties. Olpe HR. **Brain Res** 1981 Jul 6;216(1):61–71

Relationship between two voltage-dependent serotonin responses of molluscan neurones. Paupardin-Tritsch D, et al. **Brain Res** 1981 Jul 27;217(1):201–6

The uptake and fate of the radiolabeled 5-hydroxytryptamine in isolated cerebral microvessels. Spatz M, et al. **Brain Res** 1981 Sep 7; 220(1):214–9

The maturation of cortical serotonin binding sites. Uphouse LL, et al. **Brain Res** 1981 Jun;227(3):415–7

Disproportionate increases in locomotor activity in response to hormonal and photic stimuli following regional neurochemical depletions of serotonin. Waldbillig RJ, et al. **Brain Res** 1981 Jul 27;217(1):79–91

Forebrain norepinephrine and serotonin concentrations and cardiac conditioning in normal rabbits and rabbits with septal lesions. Hernández LL, et al. **Brain Res Bull** 1981 Jun;6(6):479–86

Effects of serotonin and catecholamines on RNA synthesis in planarians; in vitro and in vivo studies. Franquinet R, et al. **Cell Differ** 1981 Aug; 10(4):201–9

Catecholamines and 5-hydroxytryptamine in photophores of Porichthys notatus. Radioenzymatic detection and radioautographic localization. Anctil M, et al. **Cell Tissue Res** 1981;219(3):557–66

The antidepressant effects of trazodone and inhibition of platelet serotonin reuptake. Mann JJ, et al. **Commun Psychopharmacol** 1980; 4(4):293–301

Biogenic monoamines in early embryos of sea urchins. Manukhin BN, et al. **Dev Neurosci** 1981;4(4):322–8

Serotonin regulation of corticoid secretion in infant rats. Grota LJ. **Dev Psychobiol** 1981 May;14(3):221-8

Intraventricular administration of vasopressin and oxytocin effects the steady-state levels of serotonin, dopamine and norepinephrine in rat brain. Schwarzberg H, et al. **Endocrinol Exp (Bratisl)** 1981; 15(2):75-80

Somatostatin release from rat hypothalamus in vitro: effects of melatonin and serotonin. Richardson SB, et al. **Endocrinology** 1981 Aug; 109(2):602-6

Evidence that a serotonergic mechanism stimulates the secretion of pituitary beta-endorphin-like immunoreactivity in the rat. Sapun DI, et al. **Endocrinology** 1981 Aug;109(2):421-6

Dopaminergic and serotonergic involvement in opiate-induced prolactin release in monkeys. Wehrenberg WB, et al. **Endocrinology** 1981 Aug; 109(2):544-7

In vivo evidence for GABAergic control of serotonin release in the cat substantia nigra. Soubrié P, et al. **Eur J Pharmacol** 1981 Feb 19; 69(4):483-8

The action of 5-hydroxytryptamine and possible 5-hydroxytryptamine antagonists on neurones of the guinea-pig submucous plexus. Neild TO. **Gen Pharmacol** 1981;12(4):281-4

Effects of exposure to trichloroethylene and tetrachloroethylene on the contents of acetylcholine, dopamine, norepinephrine and serotonin in rat brain. Honma T, et al. **Ind Health** 1980;18(4):171-8

Effects of fluoxetine on a specific serotonergic syndrome in rats. Keshavan HJ, et al. **Indian J Med Res** 1981 Apr;73:653-7

Antileprosy and biological antioxidant activity of serotonin. Bergel M. **Int J Lepr** 1981 Jun;49(2):259

Release of serotonin from human platelets in vitro by radiographic contrast media. Ring J, et al. **Invest Radiol** 1981 May-Jun; 16(3):245-8

Depression of serotonin uptake by cultured endothelial cells exposed to high O2 tension. Block ER, et al. **J Appl Physiol** 1981 Jun; 50(6):1212-9

Kinetics of serotonin uptake in the dog lung. Rickaby DA, et al. **J Appl Physiol** 1981 Aug;51(2):405-14

The intracranial injection of drugs in goldfish. II. Preliminary report of behavior of serotonin as a potential hallucinogen when injected intracranially and intraabdominally. Abramson HA, et al. **J Asthma Res** 1980 Jul;17(4):175-6

Effects of noradrenergic and serotonergic neurons on blood pressure, heart rate and baroreceptor-heart rate reflex of the conscious rabbit. Korner PI, et al. **J Auton Nerv Syst** 1981 Apr;3(2-4):511-23

Increased food intake, body weight, and adiposity in rats after regional neurochemical depletion of serotonin. Waldbillig RJ, et al. **J Comp Physiol Psychol** 1981 Jun;95(3):391-405

Role of serotonin in the regulation of growth hormone and prolactin secretion in the domestic fowl. Rabii J, et al. **J Endocrinol** 1981 Sep; 90(3):355-8

Synthesis and serotonin-like activity of 2-amino-5,8-dimethoxy-6-methyl-1,2-dihydronaphthalene. Kothari PJ, et al. **J Med Chem** 1981 Jul;24(7):882-4

Cyclic AMP, 5-HT, and the modulation of transmitter release at the crayfish neuromuscular junction. Enyeart J. **J Neurobiol** 1981 Sep; 12(5):505-13

Diurnal variations in monoamine contents in discrete brain regions of the mongolian gerbil (Meriones unguiculatus). Matsumoto M, et al. **J Neurochem** 1981 Sep;37(3):792-4

Localisation of tricyclic antidepressant binding sites on serotonin nerve terminals. Sette M, et al. **J Neurochem** 1981 Jul;37(1):40-2

Neuronal responses of the globus pallidus to systemic administration of d-amphetamine: investigation of the involvement of dopamine, norepinephrine, and serotonin. Bergstrom DA, et al. **J Neurosci** 1981 Mar;1(3):292-9

The stimulus-induced release of unmetabolized 5-hydroxytryptamine from superfused rat brain synaptosomes. Collard KJ, et al. **J Neurosci Methods** 1981 Aug;4(2):163-79

Immobility test: effects of 5-hydroxytryptaminergic drugs and role of catecholamines in the activity of some antidepressants. Borsini F, et al. **J Pharm Pharmacol** 1981 Jan;33(1):33-7

(—)-m-Chlorophenyl-piperazine, a central 5-hydroxytryptamine agonist, is a metabolite of trazodone. Caccia S, et al. **J Pharm Pharmacol** 1981 Jul;33(7):477-8

A pre-junctional action of 5-hydroxytryptamine and methysergide on noradrenergic nerves in dog isolated saphenous vein. Watts AD, et al. **J Pharm Pharmacol** 1981 Aug;33(8):515-20

Substituted piperazines as central serotonin agonists: comparative specificity of the postsynaptic actions of quipazine and m-trifluoromethylphenylpiperazine. Fuller RW, et al. **J Pharmacol Exp Ther** 1981 Sep;218(3):636-41

Interaction of lithium and disulfiram in hexobarbital hypnosis: possible role of the 5-HT system. Minegishi A, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):481-7

Alteration of aminophylline-induced respiratory stimulation by perturbation of biogenic amine systems. Mueller RA, et al. **J Pharmacol Exp Ther** 1981 Sep;218(3):593-9

5-Hydroxytryptamine-induced hypothermia in rats as an in vivo model for the quantitative study of 5-hydroxytryptamine receptors. Cox B, et al. **J Pharmacol Methods** 1981 Jan;5(1):43-51

Dopamine independent rotational response to unilateral intranigral injection of serotonin. Oberlander C, et al. **Life Sci** 1981 Jun 8; 28(23):2595-601

Does high affinity [3H] imipramine binding label serotonin reuptake sites in brain and platelet? Paul SM, et al. **Life Sci** 1981 Jun 15; 28(24):2753-60

Effects of short- and long-term neuroleptic treatment on brain serotonin synthesis and turnover: focus on the serotonin hypothesis of schizophrenia. Rastogi RB, et al. **Life Sci** 1981 Aug 17;29(7):735-41

Electrophysiological evidence for the existence of separate receptor mechanisms mediating the action of 5-hydroxytryptamine. Berridge MJ. **Mol Cell Endocrinol** 1981 Jul;23(1):91-104

Immunoreactive substance P and serotonin present in the same dense-core vesicles. Pelletier G, et al. **Nature** 1981 Sep 3;293(5827):71-2

Further evidence for negative feedback control of serotonin release in the central nervous system. Baumann PA, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Aug;317(1):36-43

The noradrenaline receptor coupled adenylate cyclase system in brain. Lack of modification by changes in the availability of serotonin. Mishra R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jun; 316(3):218-24

Kinetic characteristics of newly synthesized 3H-5-HT in the brain of control and reserpinized mice. Evidence for the heterogeneous distribution of 5-HT in serotoninergic neurons. Morot-Gaudry Y, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jul;316(4):311-6

Liberation of catecholamines and 5-hydroxytryptamine from human blood-platelets. Peyer M, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb;316(1):81-6

The filum terminale of the frog spinal cord, a nontransformed glial preparation: II. Uptake of serotonin. Ritchie T, et al. **Neurochem Res** 1981 Apr;6(4):441-52

Postmortem changes of 5-hydroxytryptamine and 5-hydroxyindoleacetic acid in mouse brain and their prevention by pargyline and microwave irradiation. Van Wijk M, et al. **Neurochem Res** 1981 Apr; 6(4):425-30

The role of 5-hydroxytryptamine in dopamine-dependent stereotyped behaviour. Carter CJ, et al. **Neuropharmacology** 1981 Mar; 20(3):261-5

Accelerated metabolism of probenecid during long-term treatment of rats with anticonvulsant drugs: effect on central serotonin turnover studies. Sharpless NS. **Neuropharmacology** 1981 Mar;20(3):211-6

Effect of injury to the serotoninergic and noradrenergic brain systems on food and defensive conditioned reflexes in rats. Gromova EA, et al. **Neurosci Behav Physiol** 1981 Jan-Feb;11(1):10-5

Brain levels of noradrenalin, dopamine, and serotonin in rats with different levels of motor activity. Semenova TP, et al. **Neurosci Behav Physiol** 1981 Mar-Apr;11(2):153-5

Serotonergic projections to the spinal cord from the midbrain in the rat: an immunocytochemical and retrograde transport study. Bowker RM, et al. **Neurosci Lett** 1981 Jul 17;24(3):221-6

The immunocytochemical localization of serotonergic neurons in the rat hypothalamus. Frankfurt M, et al. **Neurosci Lett** 1981 Jul 17; 24(3):227-32

Radioautographic study of uptake and storage of indoleamines in the rabbit enterochromaffin cells. Mourre C, et al. **Neurosci Lett** 1981 May 29;23(3):251-6

Visualization of serotonin neurones in the nodose ganglia of the cat. An autoradiographic study. Gaudin-Chazal G, et al. **Neuroscience** 1981; 6(6):1027-37

Release mechanisms of 5-HT from the gastrointestinal tract in rats. Izumikawa F. **Nippon Geka Hokan** 1980 Sep 1;49(5):572-94

Effects of serotonin and L-5-hydroxytryptophan on plasma renin activity in rats. Barney CC, et al. **Pharmacol Biochem Behav** 1981 Jun; 14(6):895-900

Behavioral assessment of norepinephrine and serotonin function and interaction in the hippocampal formation. Gage FH, et al. **Pharmacol Biochem Behav** 1981 Jun;14(6):815-21

Peripheral conversion of L-5-hydroxytryptophan to serotonin induces drinking in rats. Kikta DC, et al. **Pharmacol Biochem Behav** 1981 Jun; 14(6):889-93

Brain serotonin metabolism in hibernation. Popova NK, et al. **Pharmacol Biochem Behav** 1981 Jun;14(6):773-7

Temperature preferences and the effect of changes in serotonin in maturing mice. Goodrich C, et al. **Physiol Behav** 1981 Jun; 26(6):1041-7

Effect of chloro-N-desmethyldiazepam on serum and brain tryptophan and serotonin in relation to the activity of central serotonergic neurons. Valzelli L, et al. **Pol J Pharmacol Pharm** 1981 Jan-Feb;33(1):37-42

Uterine serotonin and receptor blockade during estrogen-induced uterine hyperemia. Van Orden DE, et al. **Proc Soc Exp Biol Med** 1981 Sep; 167(4):469-74

The effect of multiple rising doses of Ro 11-2465 (serotonin uptake inhibitor) on serotonin content of human platelets. Lenehan T, et al.

Psychopharmacology (Berlin) 1981;74(1):1-3

Citalopram: a new potent inhibitor of serotonin (5-HT) uptake with central 5-HT-mimetic properties. Pawlowski L, et al. **Psychopharmacology (Berlin)** 1981;74(2):161-5

Circadian variation in the head twitch response produced by 5-methoxy-N1,N1-dimethyltryptamine and p-chloroamphetamine in the mouse. Singleton C, et al. **Psychopharmacology (Berlin)** 1981; 74(2):173-6

Evidence against the involvement of serotonergic mechanisms in wet dog shake behavior induced by carbachol chloride in rats. Turski L, et al. **Psychopharmacology (Berlin)** 1981;73(4):376-80

Release of immunoreactive serotonin into the lumen of the feline gut in response to vagal nerve stimulation. Ahlman H, et al. **Science** 1981 Sep 11;213(4513):1254-5

Lithium increases serotonin release and decreases serotonin receptors in the hippocampus. Treiser SL, et al. **Science** 1981 Sep 25; 213(4515):1529-31

5-hydroxytryptamine and adenine uptake by human blood platelets following the release reaction. Wesemann W, et al. **Thromb Res** 1981 Feb-Mar;21(4-5):367-74

SEX BEHAVIOR, ANIMAL

Conspecific odor preferences of male albino rats are reversed by intracerebral 6-hydroxydopamine. Cornwell-Jones CA. **Brain Res** 1981 Jun 1;213(2):379-85

Persistence of dihydrotestosterone inhibition of lordosis in estrogen-primed rats fed a tryptophan-deficient diet. Menniti FS, et al. **Brain Res Bull** 1981 Jul;7(1):1-4

Endocrine and behavioral effects of continuous exposure of male rats to a potent luteinizing hormone-releasing hormone (LHRH) agonist: evidence for central nervous system actions of LHRH. Dorsa DM, et al. **Endocrinology** 1981 Sep;109(3):729-35

Comparison of the effects of beta-endorphin and morphine on exploratory and socio-sexual behaviour in the male rat. Meyerson BJ. **Eur J Pharmacol** 1981 Feb 19;69(4):453-63

Estrogen facilitation of lordosis behavior in the female rat. Gorski RA, et al. **Exp Brain Res** 1981;Suppl 3:222-37

The effects of lesions of lateral tegmental noradrenergic neurons on components of sexual behavior and pseudopregnancy in female rats. Hansen S, et al. **Neuroscience** 1981;6(6):1105-17

Facilitation of mounting behavior in male rats by intracranial injections of luteinizing hormone-releasing hormone. Dorsa DM, et al. **Regul Pept** 1980 Oct;1(2):147-55

SLEEP

Suppression of active sleep by chronic treatment with chlorimipramine during early postnatal development: effects upon adult sleep and behavior in the rat. Mirmiran M, et al. **Brain Res** 1981 Jan 5; 204(1):129-46

Studies of diurnal changes in plasma renin activity, and plasma noradrenaline, aldosterone and cortisol concentrations in man. Lightman SL, et al. **Clin Endocrinol (Oxf)** 1981 Mar;14(3):213-23

Effect of a short-acting benzodiazepine on brain electrical activity during sleep. Johnson LC, et al. **Electroencephalogr Clin Neurophysiol** 1981 Jul;52(1):89-97

Effect of monoamine oxidase inhibitors on codeine disposition and pentobarbitone sleep-times in the rat. Findlay JW, et al. **J Pharm Pharmacol** 1981 Jan;33(1):45-7

Interaction of lithium and disulfiram in hexobarbital hypnosis: possible role of the 5-HT system. Minegishi A, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):481-7

Phasic activity induced by p-chlorophenylalanine in the auditory pathway. Ayala-Guerrero F, et al. **Neuropharmacology** 1981 Mar; 20(3):273-5

Dose-related effects of flurazepam on human sleep-walking patterns. Karacan I, et al. **Psychopharmacology (Berlin)** 1981;73(4):332-9

Does para-chlorophenylalanine produce disturbed waking, disturbed sleep or activation by ponto-geniculo-occipital waves in cats? Ursin R. **Waking Sleeping** 1980 Jul-Sep;4(3):211-21

[Physiological and pharmacological study of the regulation of sleep in rats] Borbély AA. **Actual Pharmacol (Paris)** 1981;33:91-104 **(Fre)**

[Effects of the intraventricular injection of methiothepin and methergoline on the sleep of rats] Laguzzi R. **C R Soc Biol (Paris)** 1981; 175(2):160-3 (Eng. Abstr.) **(Fre)**

[Current concepts of the mechanisms of regulation and target function of sleep] Moiseeva NI. **Usp Fiziol Nauk** 1981 Jun-Sep;12(3):86-105 (197 ref.) **(Rus)**

SLEEP DEPRIVATION

REM sleep deprivation induces subsensitivity of dopamine receptors mediating sedation in rats. Serra G, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):131-5

Paradoxical sleep deprivation and performance of an active avoidance task: impairment of c57BR mice and no effect in c57BL/6 mice. Kitahama K, et al. **Physiol Behav** 1981 Jul;27(1):41-50

Sleep deprivation: effects on circadian rhythms of rat brain neurotransmitter receptors. Wirz-Justice A, et al. **Psychiatry Res** 1981 Aug;5(1):67-76

[Inhibitory effect of phenazepam on protein and RNA catabolism in the supraoptic nucleus during REM-sleep deprivation] Demin NN, et al. **Fiziol Zh SSSR** 1981 Mar;67(3):460-3 **(Rus)**

SLEEP, REM

Differential effect of REM stimulating and REM inhibiting drugs (reserpine and amitriptylin) on memory. Faber J, et al. **Act Nerv Super (Praha)** 1981 Jun;23(2):169-71

REM sleep deprivation induces subsensitivity of dopamine receptors mediating sedation in rats. Serra G, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):131-5

Paradoxical sleep deprivation and performance of an active avoidance task: impairment of c57BR mice and no effect in c57BL/6 mice. Kitahama K, et al. **Physiol Behav** 1981 Jul;27(1):41-50

Post-learning paradoxical sleep, reticular activation and noradrenergic activity. Leconte P, et al. **Physiol Behav** 1981 Apr;26(4):587-94

SODIUM

Sodium and water transport in frog skin: effect of indomethacin. Bartha J, et al. **Acta Physiol Acad Sci Hung** 1981;57(1):9-17

Epidermal growth factor stimulates monovalent cation transport in isolated rat hepatocytes. Fehlmann M, et al. **Biochem Biophys Res Commun** 1981 May 15;100(1):254-60

Sodium ion and the effect of acetylcholine on phospholipid and phosphoprotein phosphate turnover in the rabbit iris smooth muscle. Abdel-Latif AA. **Biochem Pharmacol** 1981 Jun 1;30(11):1571-4

Tests of an electrostatic screening hypothesis of the inhibition of neurotransmitter release by cations at the frog neuromuscular junction. Misler S, et al. **Biophys J** 1980 Jul;31(1):9-30

Sodium-dependent relaxation in arterial smooth muscle. Gillespie MN, et al. **Clin Exp Pharmacol Physiol** 1981 May/June;8(3):209-14

Effect of hypertonic and hypotonic infusions on aldosterone in conscious sodium-depleted dogs. Childers JW, et al. **Clin Sci** 1981 Aug; 61(2):191-9

Inner medullary osmolality and sodium concentration are decreased in rats during escape from DOCA-induced salt retention. Düsing R, et al. **Clin Sci** 1981 Apr;60(4):467-9

Sodium dependency of [3H]imipramine binding in rat cerebral cortex. Briley M, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):377-80

The effect of noradrenaline on Na-K transport in rat cerebral cortical slices. Wu PH, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):529-31

Dependence on Na+ of kinetics of the lenticular Na+, K+-activated ATPase. Kern HL, et al. **Exp Eye Res** 1981 Jun;32(6):789-92

Effects of sodium loading, desoxycorticosterone acetate, and corticosterone on urinary kallikrein excretion. Bönner G, et al. **Horm Res** 1981;14(2):87-94

The activity of the lithium--sodium countertransport system in erythrocytes in depression and mania. Rybakowski J, et al. **J Affective Disord** 1981 Mar;3(1):59-64

Inhibitory effects of sodium and other monovalent cations on human platelet adenylate cyclase. Steer ML, et al. **J Biol Chem** 1981 Oct 10;256(19):9990-3

Further studies of hormone-sensitive sodium and potassium transport in red cells from developing chick embryos. Shanbaky NM, et al. **J Cell Physiol** 1981 May;107(2):303-8

Effect of reduced extracellular sodium concentration on the function of adrenal zona glomerulosa: studies in conscious rats. Balla T, et al. **J Endocrinol** 1981 Jun;89(3):411-6

Dependence of water movement on sodium transport in kidney proximal tubule: a microperfusion study substituting lithium for sodium. Corman B, et al. **J Membr Biol** 1981;62(1-2):105-11

Effects of sodium and bicarbonate ions on gamma-aminobutyric acid receptor binding in synaptic membranes of rat brain. Kurioka S, et al. **J Neurochem** 1981 Aug;37(2):418-21

Sidedness of the effects of sodium and potassium ions on the conformational state of the sodium-potassium pump. Karlish SJ, et al. **J Physiol (Lond)** 1981 Mar;312:505-29

Comparison between (RS)-nipecotic acid and GABA transport in cultured astrocytes: coupling with two sodium ions. Larsson OM, et al. **Neurochem Res** 1981 Mar;6(3):257-66

Endogenous inhibitors of Na+-independent [3H]GABA binding to crude synaptic membranes. Massotti M, et al. **Neurochem Res** 1981 May;6(5):551-65

Activation of active Na transport in sheep Purkinje fibres by external K or Rb ions. Glitsch HG, et al. **Pflugers Arch** 1981 Jul;391(1):28-34

Effect of lithium intake on sodium and lithium appetite in sodium deficient cattle. Sly J, et al. **Physiol Behav** 1981 Jul;27(1):147-52

Role of cytosolic calcium and sodium-calcium exchange in regulation of transepithelial sodium and water absorption. Taylor A. **Soc Gen Physiol Ser** 1981;36:233-59 (117 ref.)

[Histochemical localization of Na+, K+-ATPase in rat submandibular gland. The effects of mineralocorticoid and sodium ion (author's transl)] Kida T, et al. **Josai Shika Daigaku Kiyo** 1980;(9):155-8 (Eng. Abstr.) **(Jpn)**

[Changes in the alkaline cation transport across the plasma membrane of CHO-K1 cell lines resistant to ethidium bromide] Marakhova II, et al. **Tsitologiia** 1981 Apr;23(4):410-8 (Eng. Abstr.) **(Rus)**

SOMATOFORM DISORDERS

[Depression in rheumatic diseases or somatic symptoms in depression] Carrière B. **Fortschr Med** 1981 Aug 27;99(31-32):1226-30 (Eng. Abstr.) **(Ger)**

SOMATOTROPIN RELEASE INHIBITING HORMONE

Biosynthesis of somatostatin in pancreatic islets of Wistar rats and its regulation by glucose. Zühlke H, et al. **Acta Biol Med Ger** 1981;40(1):99-103

Stimulation of gastrin and somatostatin secretion from the isolated rat stomach by bombesin. DuVal JW, et al. **Am J Physiol** 1981 Sep;241(3):G242-7

Effects of somatostatin on intestinal calcium transport in the rat. Favus MJ, et al. **Am J Physiol** 1981 Sep;241(3):G215-21

Studies on the inhibition of pancreatic secretion by luminal somatostatin. Konturek SJ, et al. **Am J Physiol** 1981 Aug;241(2):G109-15

Concerning the possible existence of somatostatinergic local neuronal circuits in the rats cerebral cortex. Dorn A, et al. **Anat Anz** 1981;149(2):185-7

On the low energy solution conformation of somatostatin. Arison BH, et al. **Biochem Biophys Res Commun** 1981 Jun 16;100(3):1148-53

Somatostatin is a potent activator of phosphoprotein phosphatases in the digestive tract. Reyl F, et al. **Biochim Biophys Acta** 1981 Jul;675(2):297-300

Somatostatin-28: a conformational analysis. Wünsch E, et al. **Biopolymers** 1981 Aug;20(8):1741-5

The regional distribution of somatostatin, substance P and neurotensin in human brain. Cooper PE, et al. **Brain Res** 1981 Aug 10;218(1-2):219-32

Noradrenaline stimulates somatostatin release from incubated slices of the amygdala and the hypothalamic preoptic area. Epelbaum J, et al. **Brain Res** 1981 Jun 29;215(1-2):393-7

Release of somatostatin from extra-hypothalamic rat brain slices: inhibition by dopamine and morphine. Lee CM, et al. **Brain Res** 1981 Aug 31;219(2):355-61

Chromatographic behaviour and post-mortem stability of somatostatin in the rat and mouse brain. Lee CM, et al. **Brain Res** 1981 Sep 7;220(1):159-66

Monosodium glutamate: acute and chronic effects on rhythmic growth hormone and prolactin secretion, and somatostatin in the undisturbed male rat. Terry LC, et al. **Brain Res** 1981 Jul 27;217(1):129-42

Comparative immunocytochemical localization of enkephalin and somatostatin in the median eminence, hypothalamus and adjacent areas of the guinea-pig brain. Tramu G, et al. **Brain Res** 1981 Jun 29;215(1-2):235-55

Inhibition of anterior pituitary prostaglandin-stimulated adenylyl cyclase activity by somatostatin. Rouleau D, et al. **Can J Biochem** 1981 Apr;59(4):307-10

Somatostatin-immunoreactive fiber projections into the brain stem and the spinal cord of the rat. Krisch B. **Cell Tissue Res** 1981;217(3):531-52

Electron-microscopic immunocytochemical demonstration of separate vasotocinergic, mesotocinergic and somatostatinergic neurons in the hypothalamic magnocellular preoptic nucleus of the frog. Van Vossel-Daeninck J, et al. **Cell Tissue Res** 1981;218(1):7-12

Glucose disposal is not proportional to plasma glucose level in man. Best JD, et al. **Diabetes** 1981 Oct;30(10):847-50

Radioimmunoassay of human plasma somatostatin. Mackes K, et al. **Diabetes** 1981 Sep;30(9):728-34

Somatostatin: mechanism of action in pancreatic islet beta-cells. Pace CS, et al. **Diabetes** 1981 Oct;30(10):836-42

Insulin and glucagon breakthrough of somatostatin suppression: importance of portal vein hormone measurements. Polonsky K, et al. **Diabetes** 1981 Aug;30(8):664-9

Effects of growth hormone excess and deficiency on hypothalamic somatostatin content and release and on tissue somatostatin distribution. Berelowitz M, et al. **Endocrinology** 1981 Sep;109(3):714-9

Potent, highly selective inhibition of growth hormone secretion by position 4 somatostatin analogs. Murphy WA, et al. **Endocrinology** 1981 Aug;109(2):491-5

Somatostatin release from rat hypothalamus in vitro: effects of melatonin and serotonin. Richardson SB, et al. **Endocrinology** 1981 Aug;109(2):602-6

Combined effects of cold and somatostatin on glucose kinetics in dogs. Minaire Y, et al. **Eur J Applied Physiol** 1981;46(3):249-59

The effect of SST, glucagon, calcitonin and PGE1 on exocrine pancreatic secretion in the unrestrained dog in long-term experiments. Funovics J, et al. **Eur Surg Res** 1981;13(3):213-26

Substance P, vasoactive intestinal polypeptide (VIP) and somatostatin levels in ocular tissue of normal and sensorily denervated rabbit eyes. Unger WG, et al. **Exp Eye Res** 1981 Jun;32(6):797-801

Rapid conversion of somatostatin to active metabolite in human plasma. Märki F, et al. **FEBS Lett** 1981 May 5;127(1):22-4

Hypothalamic peptides: central nervous system control of visceral functions. Brown M, et al. **Fed Proc** 1981 Sep;40(11):2565-9 (32 ref.)

Somatostatin inhibition of glucagon-stimulated jejunal secretion in the dog. Barbezat GO, et al. **Gastroenterology** 1981 Sep;81(3):471-4

Somatostatin inhibition of basal and carbachol-stimulated gastrin release in rat antral organ culture. Harty RF, et al. **Gastroenterology** 1981 Oct;81(4):707-12

Somatostatin 28: comparison with somatostatin 14 for plasma kinetics and low-dose effects on the exocrine pancreas in dogs. Vaysse N, et al. **Gastroenterology** 1981 Oct;81(4):700-6

Somatostatin immunoreactive neurons and fibers in the hypothalamus of the newt. Fasolo A, et al. **Gen Comp Endocrinol** 1981 Jun;44(2):256-63

Comparative investigations of human and porcine somatotropin. Schleyer M, et al. **Hoppe Seylers Z Physiol Chem** 1981 Jul;362(7):875-81

Somatostatin action on insulin secretion induced by chicken and porcine vasoactive intestinal peptide in the perfused rat pancreas. Arilla E, et al. **Horm Metab Res** 1981 Jun;13(6):314-7

Development of a sensitive somatostatin radioimmunoassay and its application to plasma of stressed and non-stressed rats. Engelhardt W, et al. **Horm Metab Res** 1981 Jun;13(6):318-23

Isolation and structure of a peptide hormone predicted from a mRNA sequence. A second somatostatin from the catfish pancreas. Andrews PC, et al. **J Biol Chem** 1981 Aug 25;256(16):8267-70

Evidence for somatostatin precursors in human stomach, placenta, and amniotic fluid. Fitz-Patrick D, et al. **J Clin Endocrinol Metab** 1981 Aug;53(2):372-6

Physiological concentrations of growth hormone exert insulin-like and insulin antagonistic effects on both hepatic and extrahepatic tissues in man. MacGorman LR, et al. **J Clin Endocrinol Metab** 1981 Sep;53(3):556-9

Plasma somatostatin-like immunoreactivity during the interdigestive period in the dog. Aizawa I, et al. **J Clin Invest** 1981 Jul; 68(1):206-13

Correlation of endogenous somatostatin, gastric inhibitory polypeptide, glucagon and insulin with gastric function in the conscious calf. Bell FR, et al. **J Endocrinol** 1981 Jun;89(3):451-6

Influence of the sympatho-adrenal system and somatostatin on the secretion of insulin in the rat. Ahrén B, et al. **J Physiol (Lond)** 1981 Mar;312:563-75

High affinity binding sites for a somatostatin-28 analog in rat brain. Reubi JC, et al. **Life Sci** 1981 May 11;28(19):2191-8

Effect of prostaglandin E2 upon release of pancreatic somatostatin-like immunoreactivity. Schusdziarra V, et al. **Life Sci** 1981 May 11; 28(19):2099-102

The effect of ventromedial hypothalamic nuclei destruction on somatostatin and insulin release from the isolated perfused rat pancreas. Seino S, et al. **Life Sci** 1981 May 18;28(20):2231-6

Somatostatin modulates effects of angiotensin II in adrenal glomerulosa zone. Aguilera G, et al. **Nature** 1981 Jul 16;292(5820):262-3

Effect of chemical environment on levels of substance P and somatostatin in cultured sensory neurones. Mudge AW. **Nature** 1981 Aug 20; 292(5825):764-7

A potent cyclic hexapeptide analogue of somatostatin. Veber DF, et al. **Nature** 1981 Jul 2;292(5818):55-8

Effect of capsaicin pretreatment on capsaicin-evoked release of immunoreactive somatostatin and substance P from primary sensory neurons. Gamse R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb;316(1):38-41

Age-related changes in dopamine, LHRH and somatostatin in the rat hypothalamus. Hoffman GE, et al. **Neurobiol Aging** 1980 Summer; 1(1):27-37

Differential effects of somatostatin on the release of bioactive and immunoactive rat growth hormone in vitro. Russell SM. **Neuroendocrinology** 1981 Aug;33(2):67-72

Effects of CNS active drugs and somatostatin antiserum on growth hormone release in young and old male rats. Sonntag WE, et al. **Neuroendocrinology** 1981 Aug;33(2):73-8

Effects of intraventricular administration of neurotensin and somatostatin on thermoregulation in the rat. Chandra A, et al. **Neuropharmacology** 1981 Jul;20(7):715-8

Pharmacological characterization of scratching behaviour induced by intracranial injection of substance P and somatostatin. Dobry PJ, et al. **Neuropharmacology** 1981 Mar;20(3):267-72

New somatostatin-containing sites in the diencephalon of the neonatal rat. Shiosaka S, et al. **Neurosci Lett** 1981 Aug 7;25(1):69-73

Somatostatin-like immunoreactivity in the facial, glossopharyngeal and vagal lobes of the carp. Tohyama M, et al. **Neurosci Lett** 1981 Jul 17; 24(3):233-6

Neurotensin-like and somatostatin-like immunoreactivity within amacrine cells of the retina. Brecha N, et al. **Neuroscience** 1981;6(7):1329-40

Somatostatin receptors: identification and characterization in rat brain membranes. Srikant CB, et al. **Proc Natl Acad Sci USA** 1981 Jun; 78(6):3930-4

High biological activity of the synthetic replicates of somatostatin-28 and somatostatin-25. Brazeau P, et al. **Regul Pept** 1981 Jan;1(4):255-64

Structure-activity studies with somatostatin: the role of tryptophan in position 8. Hirst BH, et al. **Regul Pept** 1980 Oct;1(2):97-113

The effect of somatostatin and 16,16-dimethyl-prostaglandin E2 on bombesin-stimulated canine gastric acid, plasma gastrin and pancreatic polypeptide secretion. Materia A, et al. **Regul Pept** 1981 Jan; 1(4):297-305

Motilin release by intravenous infusion of nutrients and somatostatin in conscious dogs. Mori K, et al. **Regul Pept** 1981 Jan;1(4):265-70

Effect of bombesin upon plasma somatostatin-like immunoreactivity, insulin and glucagon in normal and chemically sympathectomized dogs. Schusdziarra V, et al. **Regul Pept** 1980 Oct;1(2):89-96

Is somatostatin or a somatostatin-like peptide involved in central nervous system control of gastric secretion? Taché Y, et al. **Regul Pept** 1981 Feb;1(5):307-15

Depolarization- and ionophore-induced release of octacosa somatostatin from stalk median eminence synaptosomes. Kewley CF, et al. **Science** 1981 Aug 21;213(4510):913-5

[Comparison of the in vivo biological activity of an analog of somatostatin, D-Trp8-D-Cys14-somatostatin in 2 different pharmacological models] Cazaubon C, et al. **C R Soc Biol (Paris)** 1981;175(2):200-7 (Eng. Abstr.) (Fre)

[Immunocytochemical evidence of somatostatin fibers in the neurohypophysis of the monkey Macacus irus] Girod C, et al. **C R Trav Lab Carlsberg** 1981;175(3):347-51 (Eng. Abstr.) (Fre)

[Total synthesis of somatostatin-28 (author's transl)] Moroder L, et al. **Hoppe Seylers Z Physiol Chem** 1981 Jun;362(6):697-716 (Eng. Abstr.) (Ger)

[In vitro role of some entero-insular hormones on peripheral insulin receptors] Zandomeneghi R, et al. **Boll Soc Ital Biol Sper** 1981 Apr 15;57(7):723-9 (Eng. Abstr.) (Ita)

SOMATOTROPIN RELEASING HORMONE

Inhibition of hypothalamic GnRH synthesis by inhibin. Moodbidri SB, et al. **Experientia** 1981 May 15;37(5):525-6

Evidence for a growth hormone releasing factor mediating alpha-adrenergic influence on growth hormone secretion in the rat. Eden S, et al. **Neuroendocrinology** 1981 Jul;33(1):24-7

SPACE PERCEPTION

GABA-antagonists and spatial summation in Y-type cat retinal ganglion cells. Kirby AW, et al. **J Physiol (Lond)** 1981 Mar;312:335-44

STARTLE REACTION

Pentylenetetrazol-induced enhancement of reticular formation auditory evoked potentials and acoustic startle responses in the cat. Faingold CL, et al. **Neuropharmacology** 1981 Aug;20(8):787-9

Effects of alpha-MSH and beta-endorphin on startle reflex in rat. Hoehler FK, et al. **Peptides (Fayetteville)** 1981;2 Suppl 1:137-41

Effects of 6-hydroxydopamine lesions of locus coeruleus on startle in rats. Adams LM, et al. **Psychopharmacology (Berlin)** 1981; 73(4):394-8

STEREOTYPED BEHAVIOR

Barrel rotation induced by vasopressin and involvement of dopaminergic and cholinergic functions in rats. Yamada K, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):88-94

Amphetamine behavioral toxicity: rotational behavior after chronic intrastriatal infusion. Dougherty GG Jr, et al. **Biol Psychiatry** 1981 May; 16(5):479-88

Role of dorsal mesencephalic reticular formation and deep layers of superior colliculus as out-put stations for turning behaviour elicited from the substantia nigra pars reticulata. Imperato A, et al. **Brain Res** 1981 Jul 20;216(2):437-43

Behavioural effects of cathinone, an amine obtained from Catha edulis Forsk.: comparisons with amphetamine, norpseudoephedrine, apomorphine and nomifensine. Zelger JL, et al. **Bull Narc** 1980; 32(3):67-81

Apomorphine-induced stereotypy in mature and senescent rats following cessation of chronic haloperidol treatment. Roffman M, et al. **Commun Psychopharmacol** 1980;4(4):283-6

Endogenous hyperprolactinaemia enhances amphetamine- and apomorphine-induced stereotypy. Drago F, et al. **Eur J Pharmacol** 1981 Jun 19;72(2-3):249-53

Relation between brain catecholamine receptors and dopaminergic stereotypy in rat strains. Helmeste DM, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):465-70

Effect of L-histidine and chlorcyclizine on apomorphine-induced climbing behaviour and methamphetamine stereotypy in mice. Joshi VV, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):499-502

Differential effects of dopamine agonists in mature and immature rats. McDevitt JT, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):69-75

Sequelae of 6 months continuous administration of cis(Z)-and trans(E)-flupenthixol in the rat. Waddington JL, et al. **Eur J Pharmacol** 1981 Feb 19;69(4):511-3

Effects of microinjection of 2-chloro-11 (2-dimethylaminoethoxy)-dibenzo[b,f]-thiepine (zotepine), thioridazine and haloperidol into the striatum and nucleus accumbens on stereotypic behaviour and motor activity. Lai H, et al. **J Pharm Pharmacol** 1981 Apr;33(4):252-4

Further studies on the potentiating effect of lithium chloride on methamphetamine-induced stereotypy in mice. Miyauchi T, et al. **Jpn J Pharmacol** 1981 Feb;31(1):61-8

The role of 5-hydroxytryptamine in dopamine-dependent stereotyped behaviour. Carter CJ, et al. **Neuropharmacology** 1981 Mar; 20(3):261-5

Effects of chronic haloperidol, thioridazine and zotepine treatment on apomorphine elicited stereotypic behavior and 3H-spiroperidol binding sites in the striatum of the rat. Lai HC, et al. **Proc West Pharmacol Soc** 1981;24:5-6

[Tiapride and verbal or motor stereotypies (author's transl)] Morel-Maroger A. **Sem Hop Paris** 1981 Apr 18-25;57(15-16):825-9 (Eng. Abstr.) (Fre)

STRESS, PSYCHOLOGICAL

Habitual catecholamine excretion and its relation to habitual distress. Forsman L. **Biol Psychol** 1980 Sep;11(2):83-97

Endogenous alpha-melanotropin and central dopamine systems in physical and psychological stress. Monnet F, et al. **Exp Brain Res** 1981; 42(2):203-11

The influence of foot-shock stress upon brain, pituitary and spinal cord pools of immunoreactive dynorphin in rats. Millan MJ, et al. **Neurosci Lett** 1981 Jun 12;24(1):75-9

Effects of nortriptyline treatment on learned helplessness in the rat. Telner

JI, et al. **Pharmacol Biochem Behav** 1981 Jun;14(6):823-6

Corticosterone response in group-housed rats exposed to psychogenic stresses in different social conditions. Armario A, et al. **Physiol Behav** 1981 Jul;27(1):179-81

Humoral indices of stress in rats. Natelson BH, et al. **Physiol Behav** 1981 Jun;26(6):1049-54

Relationships between sex-related psychological characteristics during adolescence and catecholamine excretion during achievement stress. Rauste-von Wright M, et al. **Psychophysiology** 1981 Jul;18(4):362-70

The stress of boredom and monotony: a consideration of the evidence. Thackray RI. **Psychosom Med** 1981 Apr;43(2):165-76

[Influence of the GABAergic system on eating behavior induced by the tail pinching technic in rats] Bereksi B, et al. **C R Trav Lab Carlsberg** 1981;175(3):323-9 (Eng. Abstr.) **(Fre)**

[Emotional stress and biochemical responses of completely recovered manic depressive patients (author's transl)] Nakahara T. **Seishin Shinkeigaku Zasshi** 1981;83(5):263-74 **(Jpn)**

[Plasma catecholamines of August and Wistar strain rats subjected to emotional stress] Kvetnanskiĭ R, et al. **Fiziol Zh SSSR** 1981 Apr; 67(4):516-23 (Eng. Abstr.) **(Rus)**

[Changes in the plasma renin activity of Wistar and August rats during emotional stress] Kvetnanskiĭ R, et al. **Fiziol Zh SSSR** 1981 Jun; 67(6):911-5 **(Rus)**

SUBSTANCE P

Contractile response of longitudinal and circular smooth muscles of guinea pig stomach and ileum to substance P. Nieber K, et al. **Acta Biol Med Ger** 1981;40(2):209-16

Tissue concentration and release of substance P-like immunoreactivity in the dental pulp. Brodin E, et al. **Acta Physiol Scand** 1981 Feb; 111(2):141-9

The role of substance P in simultaneously mediating oral pain and inflammation. Goodale DB. **Anesth Prog** 1981 Mar-Apr;28(2):41-3

Effect of substance P C-terminal heptapeptide on amylase release in rat parotid gland. Togari A, et al. **Arch Oral Biol** 1980;25(8-9):597-600

Substance P binds to the formylpeptide chemotaxis receptor on the rabbit neutrophil. Marasco WA, et al. **Biochem Biophys Res Commun** 1981 Apr 30;99(4):1065-72

Inverse relation of substance P-like immunoreactivity in dorsal raphe nucleus to serotonin levels in pons-medulla following administration of cocaine and 5-hydroxytryptophan. Pradhan S, et al. **Biochem Pharmacol** 1981 May 15;30(10):1071-6

The effects of chronic section of dorsal roots on the responsiveness of motoneurones to 5-hydroxytryptamine and a substance P analogue. Roberts MH, et al. **Br J Pharmacol** 1981 Jul;73(3):589-94

Enkephalins, substance P, bradykinin and angiotensin II: differential sites of action on the hypothalamo-neurohypophysial system. Baertschi AJ, et al. **Brain Res** 1981 Sep 7;220(1):107-19

The regional distribution of somatostatin, substance P and neurotensin in human brain. Cooper PE, et al. **Brain Res** 1981 Aug 10; 218(1-2):219-32

5-Hydroxytryptamine reduces substance P responses on dorsal horn interneurones: a possible interaction of neurotransmitters. Davies JE, et al. **Brain Res** 1981 Aug 3;217(2):399-404

Chemical characterization of substance P-like immunoreactivity in primary afferent neurones. Harmar A, et al. **Brain Res** 1981 Sep 7; 220(1):203-7

Tissue distribution of substance P in the domestic pig during postnatal development. Holzer P, et al. **Brain Res** 1981 Jun;227(3):455-9

Intrathecal substance P elicits a caudally-directed biting and scratching behavior in mice. Hylden JL, et al. **Brain Res** 1981 Jul 27; 217(1):212-5

Substance P-induced depolarization in sympathetic neurons: not simple K-inactivation. Minota S, et al. **Brain Res** 1981 Jul 6;216(1):224-8

A substance P projection to the hippocampus. Vincent SR, et al. **Brain Res** 1981 Jun 29;215(1-2):349-51

Substance P, vasoactive intestinal polypeptide (VIP) and somatostatin levels in ocular tissue of normal and sensorily denervated rabbit eyes. Unger WG, et al. **Exp Eye Res** 1981 Jun;32(6):797-801

Further support for the postsynaptic action of substance P and its blockade with baclofen in neurons of the guinea-pig hypothalamus in vitro. Ogata N, et al. **Experientia** 1981 Jul 15;37(7):759-61

Immunoreactivity for substance P in the Gasserian ganglion, ophthalmic nerve and anterior segment of the rabbit eye. Tervo K, et al. **Histochem J** 1981 May;13(3):435-43

Origin and development of VIP and substance P containing neurons in the embryonic avian gut. Fontaine-Perus J, et al. **Histochemistry** 1981; 71(3):313-23

Substance P-like immunoreactivity in the nervous system of hydra. Grimmelikhuijzen CJ, et al. **Histochemistry** 1981;71(3):325-33

Substance P-like immunoreactive nerve fibers in the trabecular meshwork. Laties AM, et al. **Invest Ophthalmol Vis Sci** 1981 Sep;21(3):484-6

Organization of substance P fibers within the hippocampal formation demonstrated with a biotin-avidin immunoperoxidase technique. Vincent SR, et al. **J Comp Neurol** 1981 Jun 10;199(1):113-23

Peptidergic innervation (substance P) in the human heart. Weihe E, et al. **J Mol Cell Cardiol** 1981 Mar;13(3):331-3

Neuropeptides in striato-nigral pathways. Cuello AC, et al. **J Neural Transm** 1981;51(1-2):83-96

Haloperidol-induced reduction of nigral substance P-like immunoreactivity: a probe for the interactions between dopamine and substance P neuronal systems. Hanson GR, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):568-74

Neurochemical studies in the hypoxic brain: substance P, met-enkephalin, GABA and angiotensin converting enzyme. Arregui A, et al. **Life Sci** 1981 Jun 29;28(26):2925-9

A synthetic peptide as an antagonist of substance P. Engberg G, et al. **Nature** 1981 Sep 17-23;293(5829):222-3

Effect of chemical environment on levels of substance P and somatostatin in cultured sensory neurones. Mudge AW. **Nature** 1981 Aug 20; 292(5825):764-7

Immunoreactive substance P and serotonin present in the same dense-core vesicles. Pelletier G, et al. **Nature** 1981 Sep 3;293(5827):71-2

Release of histamine by substance P. Erjavec F, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Aug;317(1):67-70

Effect of capsaicin pretreatment on capsaicin-evoked release of immunoreactive somatostatin and substance P from primary sensory neurons. Gamse R, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb;316(1):38-41

Time course of capsaicin-induced functional impairments in comparison with changes in neuronal substance P content. Lembeck F, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Jun;316(3):240-3

Pharmacological characterization of scratching behaviour induced by intracranial injection of substance P and somatostatin. Dobry PJ, et al. **Neuropharmacology** 1981 Mar;20(3):267-72

Demonstration of a substance P-like immunoreactivity in retinal cells of the rat. Fukuda M, et al. **Neurosci Lett** 1981 May 29;23(3):239-42

Effects of substance P on neurones and glial cells in cultured rat spinal cord. Hösli L, et al. **Neurosci Lett** 1981 Jul 2;24(2):165-8

Activation by stress of the habenulo-interpeduncular substance P neurons in the rat. Lisoprawski A, et al. **Neurosci Lett** 1981 Aug 7; 25(1):47-51

Substance P immunoreactive sensory nerves supply the rat iris and cornea. Miller A, et al. **Neurosci Lett** 1981 May 29;23(3):243-9

Substance P immunoreactive nerves in the rodent cornea. Tervo K, et al. **Neurosci Lett** 1981 Aug 7;25(1):95-7

Correlation between Met-enkephalin and substance P immunoreactivity in the primate globus pallidus. Haber S, et al. **Neuroscience** 1981; 6(7):1291-7

Regional differences in the response to substance P on the longitudinal muscle and the concentration of substance P in the digestive tract of the guinea-pig. Holzer P, et al. **Neuroscience** 1981;6(7):1433-41

Substance P and leucine-enkephalin changes after chordotomy and morphine treatment. Naftchi NE, et al. **Peptides (Fayetteville)** 1981; 2 Suppl 1:61-70

Substance P-like immunoreactivity in plasma of psychotic patients and effects of neuroleptics and electroconvulsive therapy. Kaiya H, et al. **Psychiatry Res** 1981 Aug;5(1):11-21

Neurotensin and substance P: differential effects on plasma cholesterol levels in conscious ovariectomized rats. Raju K, et al. **Regul Pept** 1981 Aug;2(4):265-74

Distinct classes of substance P receptors revealed by a comparison of the activities of substance P and some of its segments. Teichberg VI, et al. **Regul Pept** 1981 Feb;1(5):327-33

Peptide containing nerves in the nasal mucosa. Uddman R, et al. **Rhinology** 1981 Jun;19(2):75-9

Substance P in principal sympathetic neurons: regulation by impulse activity. Kessler JA, et al. **Science** 1981 Oct 16;214(4518):335-6

[The morphology of substance P in the human brain as determined by an immuno-histo-fluorescence study] Constantinidis J, et al. **Schweiz Arch Neurol Neurochir Psychiatr** 1980;127(2):323-55 (Eng. Abstr.) **(Fre)**

[The effect of substance P on the regeneration of nerve fibres in vitro (author's transl)] Lindner G, et al. **Z Mikrosk Anat Forsch** 1981; 95(3):390-4 (Eng. Abstr.) **(Ger)**

[Phospholipid metabolism in acetylcholine and substance P induced desensitization of guinea pig ileum smooth muscle] Minenko AN, et al. **Ukr Biokhim Zh** 1980 Sep-Oct;52(5):577-81 (Eng. Abstr.) **(Rus)**

SYMPATHOMIMETICS

Vascular responses to REN-293 (2-amino-3[3, 5-dihydroxyphenyl]-1-propanol hydrochloride)—a new sympathomimetic agent. Frost BR, et al. **Aust J Exp Biol Med Sci** 1981 Apr;59(Pt 2):179-82

Effects of adrenergic agonists and antagonists and of the catechol nucleus on the Na+, K+-ATPase and Mg2+-ATPase activities of synaptosomes. Sawas AH, et al. **Biochem Pharmacol** 1981 Jul 1; 30(13):1799-803

Gluconeogenesis in rabbit liver. IV. The effects of glucagon, epinephrine, alpha- and beta-adrenergic agents on gluconeogenesis and pyruvate kinase in hepatocytes given dihydroxyacetone or fructose. Yorek MA, et al. **Biochim Biophys Acta** 1981 Jul 17;675(3-4):309-15

Evidence against significant resting sympathetic coronary vasoconstrictor tone in the conscious dog. Chilian WM, et al. **Circ Res** 1981 Oct; 49(4):866-76

Relative location of alpha- and beta-adrenoceptors to sites of release of sympathetic transmitter in the rabbit facial vein. Winquist RJ, et al. **Circ Res** 1981 Aug;49(2):486-92

Differential effects of dopamine agonists in mature and immature rats. McDevitt JT, et al. **Eur J Pharmacol** 1981 Jun 10;72(1):69-75

Interaction of alpha-adrenergic imidazolines with cardiac histamine H2-receptors. Zavecz JH, et al. **Eur J Pharmacol** 1981 May 8; 71(2-3):297-306

Adrenergic drugs and intraocular pressure. Potter DE, et al. **Gen Pharmacol** 1981;12(1):1-13

Peripheral vascular effects of a new dopamine analog: 5-6-dihydroxy-2-methylaminotetralin (M-8). Maixner W, et al. **J Cardiovasc Pharmacol** 1981 Mar-Apr;3(2):381-9

The effects of alpha and beta adrenergic agonists and cyclic adenosine 3':5'-monophosphate on epidermal metabolism. Harris RR, et al. **J Invest Dermatol** 1981 Oct;77(4):337-40

SYNAPTIC RECEPTORS

Neuroleptic drug effects on neurotransmitter receptors [letter] **Am J Psychiatry** 1981 Jul;138(7):991-2

GABA-benzodiazepine-barbiturate receptor interactions. Olsen RW. **J Neurochem** 1981 Jul;37(1):1-13 (146 ref.)

Age-related alterations in neurotransmitter receptors: an electrophysiological and biochemical analysis. Lippa AS, et al. **Neurobiol Aging** 1981 Spring;2(1):3-8

Histidine modification with diethyl pyrocarbonate shows heterogeneity of benzodiazepine receptors. Burch TP, et al. **Proc Natl Acad Sci USA** 1981 Jun;78(6):3945-9

Sleep deprivation: effects on circadian rhythms of rat brain neurotransmitter receptors. Wirz-Justice A, et al. **Psychiatry Res** 1981 Aug;5(1):67-76

Studies on possible mechanisms of action of electroconvulsive therapy; effects of repeated electrically induced seizures on rat brain receptors for monoamines and other neurotransmitters. Deakin JF, et al. **Psychopharmacology (Berlin)** 1981;73(4):345-9

Hindbrain GABA receptors influence parasympathetic outflow to the stomach. Williford DJ, et al. **Science** 1981 Oct 9;214(4517):193-4

TERRITORIALITY

Territorial behavior of schizophrenics. A phylogenetic approach. Singh MM, et al. **J Nerv Ment Dis** 1981 Aug;169(8):503-12

TESTOSTERONE

Testosterone oxidation by rat liver microsomes: effects of phenobarbital pretreatment and the detection of seven metabolites by HPLC. van der Hoeven T. **Biochem Biophys Res Commun** 1981 Jun 16; 100(3):1285-91

Effects of ageing and gonadal steroid hormones on prolactin concentrations in the anterior pituitary of the chicken. Kono T, et al. **Br Poult Sci** 1980 Nov;21(6):431-6

Differential effects of gonadal steroids on dopamine metabolism in mesolimbic and nigro-striatal pathways of male rat brain. Alderson LM, et al. **Brain Res** 1981 Aug 10;218(1-2):189-206

Differential effects of estrogen and androgen on locomotor activity induced in castrated male rats by amphetamine, a novel environment, or apomorphine. Menniti FS, et al. **Brain Res** 1981 Jul 6; 216(1):89-107

Autoregulation of testosterone secretion in perfused rat testes. Darney KJ Jr, et al. **Endocrinology** 1981 Sep;109(3):993-5

Induction and maintenance of gonadotropin and lactogen receptors in hypoprolactinemic rats. Huhtaniemi IT, et al. **Endocrinology** 1981 Aug; 109(2):483-90

Endocrine correlates of sexual development in the male monkey, Macaca fascicularis. Steiner RA, et al. **Endocrinology** 1981 Sep;109(3):914-9

Effect of thyroxine, testosterone, and corticosterone on nerve growth factor (NGF) and epidermal growth factor (EGF) concentrations in adult female mouse submaxillary gland: dissociation of NGF and EGF responses. Walker P, et al. **Endocrinology** 1981 Aug;109(2):582-7

Effect of testosterone on the hypothalamic-pituitary-testicular axis of the old male rat. Larrea GA, et al. **Horm Metab Res** 1981 Jul; 13(7):396-9

Differential effects of testosterone and its metabolites on gonadotrophin secretion in the intact adult male rat. Reymond M, et al. **Horm Res** 1981;14(2):114-29

The effects of testosterone and progestins on the rate of beta-glucuronidase synthesis in mouse kidney as studied with an immunoprecipitation assay. Gupta C, et al. **Int J Androl** 1981 Jun; 4(3):342-54

Hyperprolactinemia counteracts the testosterone-induced inhibition of the preoptic area dopamine turnover. Kalra PS, et al. **Neuroendocrinology** 1981 Aug;33(2):118-22

Sexually dimorphic acquisition of a conditioned taste aversion in rats: effects of gonadectomy, testosterone replacement and water deprivation. Chambers KC, et al. **Physiol Behav** 1981 Jul;27(1):83-8

[Biological and immunological activity similar to digitalis glycosides of synthetic ACTH and some sex hormone 14-hydroxyderivatives (author's transl)] Schreiber V, et al. **Cas Lek Cesk** 1981 May 21; 120(20):616-8 (Eng. Abstr.) **(Cze)**

[Bromocriptine (Parlodel) in the treatment of pseudo-pregnancy in bitches (author's transl)] Janssens LA. **Tijdschr Diergeneeskd** 1981 Aug 1; 106(15):767-70 (Eng. Abstr.) **(Dut)**

[Reaction between steroid hormones, the liver and its plasma membrane] Denisov IuP, et al. **Biull Eksp Biol Med** 1981 Jun;91(6):722-5 (Eng. Abstr.) **(Rus)**

[Effect of the long-term administration of testosterone on induction of cytochrome P-450 in female rat live tissue using phenobarbital] Chistiakov VV, et al. **Vopr Med Khim** 1981 May-Jun;27(3):340-2 (Eng. Abstr.) **(Rus)**

THIORIDAZINE

Total and free serum haloperidol levels in schizophrenic patients and the effect of age thioridazine and fatty acid on haloperidol-serum protein binding in vitro. Rowell FJ, et al. **Br J Clin Pharmacol** 1981 Apr; 11(4):377-82

[Blood level-effect profile of thioridazine] Kühne GE, et al. **Agressologie** 1979;20(D):271-4 (Eng. Abstr.) **(Ger)**

[Influence of thioridazine on cognitive, psychomotor, and reaction performance in patients with dysthymic-depressive syndrome (author's transl)] Meyer FP, et al. **Pharmacopsychiatria** 1981 May;14(3):94-9 **(Ger)**

THIOTHIXENE

Correlation of thiothixene serum levels and age. Yesavage JA, et al. **Psychopharmacology (Berlin)** 1981;74(2):170-2

THYROID HORMONES

Syndrome of 'inappropriate secretion of thyroid-stimulating hormone' by partial target organ resistance to thyroid hormones. Salmerón De Diego J, et al. **Acta Endocrinol (Copenh)** 1981;97(3):361-8

Early auditory and visual function in normal and hyperthyroid rats. Brunjes PC, et al. **Behav Neural Biol** 1981 Apr;31(4):393-412

In vitro stimulation of human red blood cell Ca2+-ATPase by thyroid hormone. Davis PJ, et al. **Biochem Biophys Res Commun** 1981 Apr 30;99(4):1073-80

Thyroid hormone synthesis in thyroglobulin. The mechanism of the coupling reaction. Gavaret JM, et al. **J Biol Chem** 1981 Sep 10; 256(17):9167-73

Thyroid hormone dependency in immature but not mature grafted locus coeruleus neurons. Evidence from intraocular innervation of iris transplants. Granholm AC, et al. **Med Biol** 1981 Feb;59(1):51-7

Tricyclic antidepressants do not alter thyroid hormone levels in patients suffering from a major affective disorder. Linnoila M, et al. **Psychiatry Res** 1981 Jun;4(3):357-60

Effect of anticonvulsant and antidepressant drugs on iodothyronines in serum. Liewendahl K, et al. **Scand J Clin Lab Invest** 1980; 40(8):767-74

Changes in certain diurnal hormonal rhythms in developing male rats exposed to adiurnal environmental cues. Ooka-Souda S. **Mech Ageing Dev** 1981 Mar;15(3):227-33 **(eng)**

THYROTROPIN

Syndrome of 'inappropriate secretion of thyroid-stimulating hormone' by partial target organ resistance to thyroid hormones. Salmerón De Diego J, et al. **Acta Endocrinol (Copenh)** 1981;97(3):361-8

Long lasting amplification and deformation of thyroid receptors after thyrotropin (TSH) and gonadotropin (GTH) treatment of chickens in the foetal period. Nagy SU, et al. **Acta Physiol Acad Sci Hung** 1980; 56(3):303-7

Dose dependence of the thyrotropin (TSH) receptor damaging effect of gonadotropin in the newborn rats. Nagy SU, et al. **Acta Physiol Acad Sci Hung** 1980;56(4):417-20

TSH, HGH, HPr, and cortisol response to TRH in depressed patients. Ramseier F, et al. **Acta Psychiatr Belg** 1980 Jul-Aug;80(4):399-409

Ultrastructural and cytochemical effects of trypan blue on TSH stimulation of thyroid follicular cells. Payer AF, et al. **Cell Tissue Res** 1981;218(3):547-56

Norepinephrine and thyrotropin effects on the thyroid in vitro: simultaneous stimulation of iodide organification and antagonism of thyroxine release. Maayan ML, et al. **Endocrinology** 1981 Sep; 109(3):930-4

Effects of various prostanoids on thyrotropin secretion by superfused anterior pituitary cells. Wright KC, et al. **Endocrinology** 1981 Aug; 109(2):637-43

Domperidone directly stimulates TSH secretion in vitro. Powell R, et al. **FEBS Lett** 1981 Jun 29;129(1):97-9

Dynamics and regulation of TSH secretion by superfused anterior pituitary cells. Connors JM, et al. **Horm Res** 1981;14(1):1-17

Studies on the role of the pineal gland in the regulation of TSH secretion in postpuberal male rats. Mattila J, et al. **Horm Res** 1981; 14(1):24-35

Thyrotropin-dependence of the distribution of peroxidase in rat thyroid gland. Matsukawa S, et al. **Tohoku J Exp Med** 1981 Apr; 133(4):431-43

THYROXINE

Effect of ovariectomy, thyroidectomy and of thyroxine treatment on the plasma level of corticosterone of the female Japanese quail. Péczely P, et al. **Acta Biol Acad Sci Hung** 1981;32(1):1-6

Plasma corticosterone, thyroxine and triiodothyronine level in the collared dove (Streptopelia decaocto) during the reproductive cycle. Péczely P, et al. **Acta Physiol Acad Sci Hung** 1980;56(4):421-30

GDP binding to rat brown fat mitochondria: effects of thyroxine at different ambient temperatures. Sundin U. **Am J Physiol** 1981 Sep; 241(3):C134-9

Ratio of thyroxine to thyroxine-binding globulin. An assessment of the validity of a single reference range. Cusick CF. **Ann Clin Biochem** 1981 Mar;18(2):93-6

Circulating thyroxine levels in institutionalized children. Perassi NI, et al. **Arch Int Physiol Biochim** 1980 Dec;88(5):491-5

Chloramphenicol inhibits hormone-dependent induction of cytoplasmic mRNA coding for the mitochondrial enzyme, carbamyl phosphate synthetase, in Rana catesbeiana tadpoles. Pouchelet M, et al. **Biochim Biophys Acta** 1981 Jun 26;654(1):67-76

Identification of an intracellular pathway of thyroxine synthesis by dispersed thyroid cells. Rousset B, et al. **Biochim Biophys Acta** 1981 Aug 5;676(1):8-18

Further observations on serum free thyroxine concentrations during pregnancy. Boss AM, et al. **Br Med J [Clin Res]** 1981 Aug 29; 283(6291):584

Lack of a relationship between concentrations of plasma luteinising hormone, thyroxine and prolactin at nine week's of age and subsequent egg production in the domestic hen. Sharp PJ, et al. **Br Poult Sci** 1981 Jan;22(1):53-8

Thyroxin dependency of the developing locus coeruleus. Evidence from intraocular grafting experiments. Seiger A, et al. **Cell Tissue Res** 1981; 220(1):1-15

Evaluation of free thyroxin measurements in patients with non-thyroidal illnesses. Lawlor JF, et al. **Clin Chem** 1981 Aug;27(8):1457-9

Cardiac beta-adrenoreceptors in the thyroxine-treated dog. Ho K, et al. **Clin Exp Pharmacol Physiol** 1981 Mar-Apr;8(2):183-7

The effect of thyroxine on transparency and PAPS synthesis in the avian cornea. Beckenhauer DM, et al. **Dev Biol** 1981 May;84(1):225-9

Propranolol and thyroxine metabolism [letter] Nester TJ. **Drug Intell Clin Pharm** 1981 Feb;15(2):131-2

Norepinephrine and thyrotropin effects on the thyroid in vitro: simultaneous stimulation of iodide organification and antagonism of thyroxine release. Maayan ML, et al. **Endocrinology** 1981 Sep; 109(3):930-4

Effect of thyroxine, testosterone, and corticosterone on nerve growth factor (NGF) and epidermal growth factor (EGF) concentrations in adult female mouse submaxillary gland: dissociation of NGF and EGF responses. Walker P, et al. **Endocrinology** 1981 Aug;109(2):582-7

The influence of thyroid gland and thyroxine on the acetylcholinesterase activity of rat brain and adenohypophysis. Owasoyo JO, et al. **Endokrinologie** 1981 Apr;77(2):242-6

Kinetics of thyroglobulin iodination and thyroid hormone synthesis catalyzed by peroxidases: the role of H2O2. Virion A, et al. **Eur J Biochem** 1981 Jun;117(1):103-9

Effect of thyroid hormone on the regeneration of the hypoglossal nerve in rats. Yu WH, et al. **Exp Neurol** 1981 Jul;73(1):325-9

Specific anti-thyroxine antisera induced by thyroxine sensitized liposomes. Tan CT, et al. **Immunol Commun** 1981;10(1):27-34

Role of thyroxine & gonadotropins on the mobilization of ovarian cholesterol in a teleost Anabas testudineus (Bloch). Sen S, et al. **Indian J Exp Biol** 1981 May;19(5):408-12

The relationship of thyroxine secretion rate to growth of swine. Marple DN, et al. **J Anim Sci** 1981 Mar;52(3):500-4

Ion transport in liver mitochondria from normal and thyroxine-treated rats. Shears SB, et al. **J Bioenerg Biomembr** 1980 Dec; 12(5-6):379-93

Influence of thyroxine on suckling rat intestinal alkaline phosphatase and effects of undernutrition on the same. Subramoniam A, et al. **J Exp Zool** 1980 Dec;214(3):317-22

Retinotectal reorganization in goldfish-III. Effect of thyroxine. Marotte LR, et al. **Neuroscience** 1981;6(8):1591-600

The potentiation of ozone toxicity by thyroxine. Wong DS, et al. **Res Commun Chem Pathol Pharmacol** 1981 Mar;31(3):483-92

[Measurement of free thyroxine in serum with radioimmunoassay (author's transl)] Mitsuma T, et al. **Horumon To Rinsho** 1981 Jan;29(1):127-31 **(Jpn)**

[Studies on free thyroxine measurement with radioimmunoassay kit -evaluation of GammaCoat free T4 kit (author's transl)] Nakagawa T, et al. **Kaku Igaku** 1981 Apr;18(3):385-400 **(Jpn)**

[Studies on the measurement of serum thyroxine with 'Amerlex T4 RIA' kit (author's transl)] Watanabe S, et al. **Kaku Igaku** 1981 Apr; 18(3):333-8 **(Jpn)**

[Structuro-metabolic integration of gastric endocrine cells in the presence of a disruption in hormone balance] Fedchenko SN. **Arkh Anat Gistol Embriol** 1981 Mar;80(3):68-77 (Eng. Abstr.) **(Rus)**

TRANQUILIZING AGENTS

Formation of nitroso compounds and mutagens from tranquilizers by drug/nitrite interaction. Takeda Y, et al. **Cancer Lett** 1981 Mar; 12(1-2):81-6

Cuban women, sex role conflicts and the use of prescription drugs. González DH, et al. **J Psychoactive Drugs** 1981 Jan-Mar; 13(1):47-51

Central action of mepiprazole. Maj J, et al. **Pol J Pharmacol Pharm** 1980 Jul-Aug;32(4):475-84

Drugs used to produce standing chemical restraint in horses. Muir WW. **Vet Clin North Am [Large Anim Pract]** 1981 May;3(1):17-44 (128 ref.)

[Tranquilizers] Ferrand I. **Soins Psychiatr** 1981 Jan;(7):33-6 **(Fre)**

TRANQUILIZING AGENTS, MAJOR

Overall-response parameter analysis applied to butyrophenones. Mager PP. **Act Nerv Super (Praha)** 1981 Jun;23(2):130-5

Neuroleptic drug effects on neurotransmitter receptors [letter] **Am J Psychiatry** 1981 Jul;138(7):991-2

Prescription of neuroleptic drugs by family practice residents [letter] Holt RJ, et al. **Am J Psychiatry** 1981 Aug;138(8):1129

Effect of neuroleptics on indoleamine-N-methyltransferase activity and brain metabolism of bufotenin. Gomes UC, et al. **Biochem Pharmacol** 1981 Mar 15;30(6):571-5

Neuroleptics decrease blinking in schizophrenic subjects. Karson C, et al. **Biol Psychiatry** 1981 Jul;16(7):679-82

Evidence for an inhibitory presynaptic component of neuroleptic drug action. de Belleroche JS, et al. **Br J Pharmacol** 1981 Mar; 72(3):427-33

The constitutional right to refuse antipsychotic medications. Brooks AD. **Bull Am Acad Psychiatry Law** 1980;8(2):179-221

Rapid parenteral treatment of acute psychosis. Menuck M, et al. **Compr Psychiatry** 1981 Jul-Aug;22(4):351-61 (69 ref.)

Pre- and postsynaptic alpha-adrenoceptor antagonism by neuroleptics in vivo. Petersen EN. **Eur J Pharmacol** 1981 Feb 19;69(4):399-405

Differential changes in DOPAC levels in the hippocampal formation, septum and striatum of the rat induced by acute and repeated neuroleptic treatment. Scatton B. **Eur J Pharmacol** 1981 May 22;71(4):499-503

Using drug holidays for chronic outpatients. Sharer DR, et al. **Hosp Community Psychiatry** 1981 Jun;32(6):420-1

Identification and distribution of neuroleptic binding sites in the rat spinal cord. Demenge P, et al. **J Neurochem** 1981 Jul;37(1):53-9

Effects of microinjection of 2-chloro-11 (2-dimethylaminoethoxy)-dibenzo[b,f]-thiepine (zotepine), thioridazine and haloperidol into the striatum and nucleus accumbens on stereotypic behaviour and motor activity. Lai H, et al. **J Pharm Pharmacol** 1981 Apr;33(4):252-4

Comparative effects of classical and atypical antipsychotic drugs in combination with a non-amphetamine stimulant on rat brain dopamine metabolism. McMillen BA. **J Pharm Pharmacol** 1981 Aug; 33(8):544-6

Neuroleptic drugs activate tyrosine hydroxylase of retinal amacrine cells. Cohen J, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):390-4

During one year's neuroleptic treatment in rats striatal dopamine receptor blockade decreases but serum prolactin levels remain elevated. Dyer RG, et al. **Life Sci** 1981 Jan 12;28(2):167-74

Risks of antipsychotic drugs overemphasized [letter] Baldessarini RJ, et al. **N Engl J Med** 1981 Sep 3;305(10):588-9

A double-blind comparison of bromperidol and haloperidol in newly admitted schizophrenic patients. Brannen JO, et al. **Pharmacopsychiatria** 1981 Jul;14(4):139-40

Effects of chronic haloperidol, thioridazine and zotepine treatment on apomorphine elicited stereotypic behavior and 3H-spiroperidol binding sites in the striatum of the rat. Lai HC, et al. **Proc West Pharmacol Soc** 1981;24:5-6

A follow-up study of schizophrenic outpatients treated with depot-neuroleptics. Tegeler J, et al. **Prog Neuropsychopharmacol** 1981; 5(1):79-90

Effects of long-term neuroleptic use on brain density. Lyon K, et al. **Psychiatry Res** 1981 Aug;5(1):33-7

Acute amphetamine response predicts antidepressant and antipsychotic responses to lithium carbonate in schizophrenic patients. van Kammen DP, et al. **Psychiatry Res** 1981 Jun;4(3):313-25

(Des-Tyr)-gamma-endorphin in the treatment of schizophrenia. Manchanda R, et al. **Psychol Med** 1981 May;11(2):401-4

Antagonism of reserpine rigidity without inducing sedation. Southwick

S, et al. **Psychopharmacology (Berlin)** 1981;74(1):29-32

[On the question of differences between therapeutic responses after particular neuroleptics in comparison to perphenazine in schizophrenics (author's transl)] Náhunek K, et al. **Cesk Psychiatr** 1981 Feb; 77(1):25-30 (Eng. Abstr.) **(Cze)**

[Mechanism of action and indications for psychopharmaceutic agents; possibilities and limitations in the elderly] Verhoeven WM. **Gerontologie** 1981 Aug;12(3):126-38 (Eng. Abstr.) **(Dut)**

[Diltiazem and anaesthesia] Zerr C, et al. **Ann Cardiol Angeiol (Paris)** 1981 Mar-Apr;30(2):133-7 **(Fre)**

[Influence of the procedure of administration in the activity of some antidepressant or disinhibiting drugs upon behavioural despair (author's transl)] Scotto di Tella AM, et al. **J Pharmacol** 1981 Apr-Jun; 12(2):179-88 (Eng. Abstr.) **(Fre)**

[High-dosed neuroleptic therapy] Platz T, et al. **Pharmacopsychiatria** 1981 Jul;14(4):141-7 (82 ref.) (Eng. Abstr.) **(Ger)**

TRANQUILIZING AGENTS, MINOR

Use of gastric fistula rats for the study of sedative, hypnotic and antianxiety drugs. Nozaki M, et al. **Drug Alcohol Depend** 1981 Jun; 7(3):221-31

Action of pyrazolopyridines as modulators of [3H]flunitrazepam binding to the gaba/benzodiazepine receptor complex of the cerebellum. Supavilai P, et al. **Eur J Pharmacol** 1981 Mar 12;70(2):183-93

Septal driving of hippocampal theta rhythm: a role for gamma-aminobutyrate in the effects of minor tranquillizers? Mellanby J, et al. **Neuroscience** 1981;6(7):1412-21

Effects of buspirone on conflict behavior of laboratory rats and monkeys. Hartmann RJ, et al. **Proc West Pharmacol Soc** 1981;24:179-81

Antianxiety agents and emotional behavior, an information processing analysis. Morris MD, et al. **Prog Neuropsychopharmacol** 1981; 5(3):219-40

Anxiolytics antagonize yohimbine's discriminative stimulus properties. Browne RG. **Psychopharmacology (Berlin)** 1981;74(3):245-9

[Clinical manifestations and treatment of addictions to hypnotics and mild tranquilizers] Shen YC.
Chung Hua Shen Ching Ching Shen Ko Tsa Chih 1980 Apr; 13(4):200-1 **(Chi)**

[Stimulation of prostaglandin E2 and F2a biosynthesis in the brains of mouse strain F1 (CBA X C57BL) by the tranquilizer phenazepam] Romantsev EF, et al. **Dokl Akad Nauk SSSR** 1981;258(1):239-42 **(Rus)**

[Anxiety; pharmacological bases of treatment] de Andrés Rodriguez-Trelles F. **An R Acad Nac Med (Madr)** 1981; 98(1):69-116 (68 ref.) **(Spa)**

TRANYLCYPROMINE

Rapid response of severe obsessive-compulsive disorder to tranylcypromine. Jenike MA. **Am J Psychiatry** 1981 Sep; 138(9):1249-50

Addiction to tranylcypromine. Griffin N, et al. **Br Med J [Clin Res]** 1981 Aug 1;283(6287):346

Comparison of molindone and tranylcypromine in the treatment of refractory depression. Small JG, et al. **J Clin Pharmacol** 1981 Aug-Sep; 21(8-9):351-8

Amphetamine and tranylcypromine in an animal model of depression: pharmacological specificity of the reversal effect. Katz RJ, et al. **Neurosci Biobehav Rev** 1981 Summer;5(2):259-64

TRIFLUOPERAZINE

Calmodulin antagonists modulate rabbit neutrophil degranulation, aggregation and stimulated oxygen consumption. Alobaidi T, et al. **Biochim Biophys Acta** 1981 Jul 17;675(3-4):316-21

Sensitive gas chromatographic determination of trifluoperazine in human plasma. Gillespie TJ, et al. **J Chromatogr** 1981 Apr 10;223(1):95-102

Modulation of platelet shape and membrane receptor binding by Ca2+-calmodulin complex. Kao KJ, et al. **Nature** 1981 Jul 2; 292(5818):82-4

TRYPTAMINES

Characterization of eight biogenic indoleamines as substrates for type A and type B monoamine oxidase. Suzuki O, et al. **Biochem Pharmacol** 1981 Jun 1;30(11):1353-8

Different hypothalamic receptors mediate 5-hydroxytryptamine- and tryptamine-induced core temperature changes in the rat. Cox B, et al. **Br J Pharmacol** 1981 Mar;72(3):477-82

TRYPTOPHAN

Blood-brain transport of tryptophan and phenylalanine: effect of portacaval shunt in dogs. Huet PM, et al. **Am J Physiol** 1981 Aug; 241(2):G163-9

Tryptophan metabolism in children with attentional deficit disorder. Irwin M, et al. **Am J Psychiatry** 1981 Aug;138(8):1082-5

Nanosecond fluorometry and the luminescence of biological macromolecules. Brand L, et al. **Ann NY Acad Sci** 1981; 366:197-207

A new component in protein fluorescence. Longworth JW. **Ann NY Acad Sci** 1981;366:237-45

Middle molecular weight substances and tryptophan in cerebrospinal fluid of schizophrenic patients. Sperschneider H, et al. **Artif Organs** 1981 May;5(2):177-8

Measurement of distance between fluorescent amino acid residues and metal ion binding sites. Quantitation of energy transfer between tryptophan and terbium(III) or europium(III) in thermolysin. Horrocks WD Jr, et al. **Biochem Biophys Res Commun** 1981 May 15; 100(1):111-7

Tryptophan fluorescence of human hemoglobin. I. Significant change of fluorescence intensity and lifetimes in the T - R transition. Itoh M, et al. **Biochem Biophys Res Commun** 1981 Jun 16;100(3):1259-65

Formation of mutagens from tryptophan by the reaction with nitrite. Ohta T, et al. **Biochem Biophys Res Commun** 1981 May 15;100(1):52-7

Effects of benserazide and carbidopa on the metabolism of L-tryptophan by isolated rat liver cells. Smith SA, et al. **Biochem Pharmacol** 1981 Mar 15;30(6):623-8

Role of tryptophanyl and tyrosyl residues of flavoproteins in binding with flavin coenzymes. X-ray structural studies using model complexes. Inoue M, et al. **Biochemistry** 1981 May;20(10):2936-45

Laser chemically induced dynamic nuclear polarization study of the reaction between photoexcited flavins and tryptophan derivatives at 360 MHz. McCord EF, et al. **Biochemistry** 1981 May;20(10):2880-8

Pausing of RNA polymerase during in vitro transcription of the tryptophan operon leader region. Winkler ME, et al. **Biochemistry** 1981 Jun 23;20(13):3738-44

Nanosecond segmental mobilities of tryptophan residues in proteins observed by lifetime-resolved fluorescence anisotropies. Lakowicz JR, et al. **Biophys J** 1980;32(1):591-601

Distributive profiles of free and protein-incorporated tryptophan and valine in cerebral cortex slices from adult and 2-day-old rats. Korpi ER, et al. **Brain Res** 1981 Jul 6;216(1):219-23

Developmental changes in brain indoles, serum tryptophan and other serum neutral amino acids in the rat. Zeisel SH, et al. **Brain Res** 1981 Jul;227(4):551-64

Persistence of dihydrotestosterone inhibition of lordosis in estrogen-primed rats fed a tryptophan-deficient diet. Menniti FS, et al. **Brain Res Bull** 1981 Jul;7(1):1-4

Mutagenicities of gamma-carboline derivatives related to potent mutagens found in tryptophan pyrolysates. Nagao M, et al. **Carcinogenesis** 1980 May;1(5):451-4

Evidence that a serotonergic mechanism stimulates the secretion of pituitary beta-endorphin-like immunoreactivity in the rat. Sapun DI, et al. **Endocrinology** 1981 Aug;109(2):421-6

The rates of photodestruction of tryptophan residues in human and bovine ocular lens proteins. Borkman RF, et al. **Exp Eye Res** 1981 Jun; 32(6):747-54

Cerebrospinal fluid amine metabolites, tryptophan and clinical parameters in depression. Part 1. Background variables. Banki CM, et al. **J Affective Disord** 1981 Jun;3(2):81-9

Relevance of tryptophan and tyrosine availability in endogenous and 'non-endogenous' depressives treated with imipramine or clomipramine. Møller SE, et al. **J Affective Disord** 1981 Sep;3(3):231-44

Dynamics of amino acid side chains in membrane proteins by high field solid state deuterium nuclear magnetic resonance spectroscopy. Phenylalanine, tyrosine, and tryptophan. Kinsey RA, et al. **J Biol Chem** 1981 Sep 10;256(17):9028-36

Analysis of some tryptophan and phenylalanine metabolites in urine by a straight-phase high-performance liquid chromatographic technique. Ghebregzabher M, et al. **J Chromatogr** 1981 Feb 13;222(2):191-201

Xanthurenic acid excretion in urine after oral intake of 5 grams L-tryptophan by healthy volunteers: standardisation of the reference values. Hoes MJ, et al. **J Clin Chem Clin Biochem** 1981 May; 19(5):259-64

Metabolism of tryptophan by Pseudomonas aureofaciens and its relationship to pyrrolnitrin biosynthesis. Salcher O, et al. **J Gen Microbiol** 1980 Dec;121(Pt. 2):465-71

Nucleotide sequence of Escherichia coli trpE. Anthranilate synthetase component I contains no tryptophan residues. Nichols BP, et al. **J Mol Biol** 1981 Feb 15;146(1):45-54

Indolic substances in plasma, cerebrospinal fluid, and frontal cortex of human subjects infused with saline or tryptophan. Gillman PK, et al. **J Neurochem** 1981 Aug;37(2):410-7

The effect of insulin upon the influx of tryptophan into the brain of the rabbit. Daniel PM, et al. **J Physiol (Lond)** 1981 Mar;312:551-62

Dietary tryptophan and aggressive behavior in rats. **Nutr Rev** 1981 Jul; 39(7):284-5

Influence of unilateral ECT on tryptophan metabolism in endogenous depression. Smith DF, et al. **Pharmacopsychiatria** 1981 Jul;

14(4):135-8

Effect of chloro-N-desmethyldiazepam on serum and brain tryptophan and serotonin in relation to the activity of central serotonergic neurons. Valzelli L, et al. **Pol J Pharmacol Pharm** 1981 Jan-Feb;33(1):37-42

Tandem termination sites in the tryptophan operon of Escherichia coli. Wu AM, et al. **Proc Natl Acad Sci USA** 1981 May;78(5):2913-7

Decreased tryptophan availability in endogenous depression caused by disturbed plasma leucine clearance. Møller SE, et al. **Prog Neuropsychopharmacol** 1981;5(3):277-9

Structure-activity studies with somatostatin: the role of tryptophan in position 8. Hirst BH, et al. **Regul Pept** 1980 Oct;1(2):97-113

TRYPTOPHAN HYDROXYLASE

Maternal influences on tryptophan hydroxylase activity in embryonic rat brain. Lauder JM, et al. **Dev Neurosci** 1981;4(4):291-5

A calmodulin-dependent protein kinase that is involved in the activation of tryptophan 5-monooxygenase is specifically distributed in brain tissues. Yamauchi T, et al. **FEBS Lett** 1981 Jun 29;129(1):117-9

Interaction between the oxygen and tryptophan dependence of synaptosomal tryptophan hydroxylase. Katz IR. **J Neurochem** 1981 Aug; 37(2):447-51

Stability properties of activated tryptophan hydroxylase from rat midbrain. Vitto A, et al. **J Neurochem** 1981 Sep;37(3):601-7

Effects of norepinephrine on pineal tryptophan hydroxylase, using an improved [14C]CO2-trapping microtechnique. Chan A, et al. **J Pharmacol Methods** 1981 Aug;6(1):13-20

Biopterin. VII. Inhibition of synthesis of reduced biopterins and its bearing on the function of cerebral tryptophan-5-hydroxylase in vivo. Gál EM, et al. **Neurochem Res** 1981 Mar;6(3):233-41

TYROSINE

A new component in protein fluorescence. Longworth JW. **Ann NY Acad Sci** 1981;366:237-45

Laser Raman spectroscopy of adrenal iron-sulfur apoprotein: the anomalous tyrosine residue at position 82. Bicknell-Brown E, et al. **Biochem Biophys Res Commun** 1981 Jul 16;101(1):298-305

Role of tryptophanyl and tyrosyl residues of flavoproteins in binding with flavin coenzymes. X-ray structural studies using model complexes. Inoue M, et al. **Biochemistry** 1981 May;20(10):2936-45

Internal dynamics of proteins. Short time and long time motions of aromatic sidechains in PTI. Karplus M, et al. **Biophys J** 1980; 32(1):603-18

Epidermal growth factor induces rapid tyrosine phosphorylation of proteins in A431 human tumor cells. Hunter T, et al. **Cell** 1981 Jun; 24(3):741-52

Syntheses of L-tyrosine-related amino acids by tyrosine phenol-lyase of Citrobacter intermedius. Nagasawa T, et al. **Eur J Biochem** 1981 Jun; 117(1):33-40

Stimulation of synaptosomal tyrosine hydroxylation by phencyclidine in vitro. Vickroy TW, et al. **Eur J Pharmacol** 1981 May 22; 71(4):463-73

Tyrosine aminotransferase as the rate-limiting step for tyrosine catabolism in isolated rat liver cells. Dickson AJ, et al. **FEBS Lett** 1981 May 5; 127(1):28-32

H NMR studies of Tyr-237 of lactate dehydrogenase. Parker DM, et al. **FEBS Lett** 1981 Jun 29;129(1):33-5

Adjuvant activity of 6-amino-6-deoxy-muramyldipeptides and their acylamino derivatives on the induction of delayed hypersensitivity to azobenzenearsonate-N-acetyl-L-tyrosine in guinea pigs. Azuma I, et al. **Infect Immun** 1981 Jun;32(3):1305-8

Relevance of tryptophan and tyrosine availability in endogenous and 'non-endogenous' depressives treated with imipramine or clomipramine. Møller SE, et al. **J Affective Disord** 1981 Sep;3(3):231-44

The structure of hemoglobin Creteil (beta 89 Ser replaced by Asn) is similar to that of abnormal human hemoglobins having sequence changes at Tyr 145 beta. Arnone A, et al. **J Biol Chem** 1981 Aug 25; 256(16):8545-52

Dynamics of amino acid side chains in membrane proteins by high field solid state deuterium nuclear magnetic resonance spectroscopy. Phenylalanine, tyrosine, and tryptophan. Kinsey RA, et al. **J Biol Chem** 1981 Sep 10;256(17):9028-36

Preferential action of a brain detyrosinolating carboxypeptidase on polymerized tubulin. Kumar N, et al. **J Biol Chem** 1981 Jul 25; 256(14):7678-86

Selective dephosphorylation of proteins containing phosphotyrosine by alkaline phosphatases. Swarup G, et al. **J Biol Chem** 1981 Aug 10; 256(15):8197-201

Mechanism of smooth muscle relaxation by tiropramide. Vidal y Plana RR, et al. **J Pharm Pharmacol** 1981 Jan;33(1):19-24

Purified low-molecular-weight protein kinase from murine sarcoma virus particles catalyzes tyrosine phosphorylation endogenously but phosphorylates cellular proteins at serine. Sen A. **J Virol** 1981 Aug; 39(2):612-24

Tyrosine availability and dopamine synthesis in the striatum: studies with gamma-butyrolactone. Sved A, et al. **Life Sci** 1981 Aug 17; 29(7):743-8

Quercetin inhibits tyrosine phosphorylation by the cyclic nucleotide-independent, transforming protein kinase, pp60src. Glossmann H, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Aug; 317(1):100-2

Dietary phenylalanine and tyrosine interrelationships in the Sprague-Dawley rat. Elkin RG, et al. **Proc Soc Exp Biol Med** 1981 Jul;167(3):310-7

[Effect of minaprine on the metabolism of tyrosine in the rat] Topall G, et al. **Agressologie** 1981;22(2):55-7 (Eng. Abstr.) **(Fre)**

[Localization of tyrosine residues in histone H1 from wheat embryos] Odintsova TI, et al. **Biokhimiia** 1981 Jan;46(1):162-71 (Eng. Abstr.) **(Rus)**

TYROSINE AMINOTRANSFERASE

Glucocorticoid induction of tyrosine aminotransferase in kidney cortex. Elam L, et al. **Biochem Biophys Res Commun** 1981 Jun 16; 100(3):1143-7

Induction of tyrosine aminotransferase by pyridoxine in Drosophila hydei. Belew K, et al. **Chromosoma** 1981;82(1):99-106

Tyrosine aminotransferase as the rate-limiting step for tyrosine catabolism in isolated rat liver cells. Dickson AJ, et al. **FEBS Lett** 1981 May 5; 127(1):28-32

NADH-coupled spectrophotometric assay of tyrosine aminotransferase. Di Cola D, et al. **Ital J Biochem** 1981 Jan-Feb;30(1):30-9

Physical properties, limited proteolysis, and acetylation of tyrosine aminotransferase from rat liver. Hargrove JL, et al. **J Biol Chem** 1981 Aug 10;256(15):8012-7

Ontogenesis of the adrenal glucocorticoids and of the target function of the enzymatic tyrosine transaminase activity in the chick embryo. Marie C. **J Endocrinol** 1981 Aug;90(2):193-200

[Multiple forms of tyrosine aminotransferase in rat liver cells and their role in cell homeostasis] Mertvetsov NP. **Vopr Med Khim** 1981 Mar-Apr;27(2):154-66 (Eng. Abstr.) **(Rus)**

TYROSINE HYDROXYLASE

Evidence for a dual effect of dibutyryl cyclic AMP on the synthesis of tyrosine aminotransferase in rat liver. Granner D, et al. **Adv Cyclic Nucleotide Res** 1981;14:529-37

Regulation by catecholamines of spontaneous growth hormone secretion in the baboon. Stewart JK, et al. **Am J Physiol** 1981 Sep; 241(3):E196-9

Tyrosine 3-monoxygenase is phosphorylated by Ca2+-, calmodulin-dependent protein kinase, followed by activation by activator protein. Yamauchi T, et al. **Biochem Biophys Res Commun** 1981 May 29;100(2):807-13

Catecholamine levels and tyrosine hydroxylase activities in rat brain regions after chronic treatment with, and withdrawal of, methamphetamine. Bardsley ME, et al. **Biochem Pharmacol** 1981 Jun 15;30(12):1543-9

Inactivation of tyrosine 3-monooxygenase by acetone precipitation and its restoration by incubation with a sulfhydryl agent and iron. Okuno S, et al. **Biochim Biophys Acta** 1981 Apr 14;658(2):327-33

Chemical deafferentation of the olfactory bulb: plasticity of the levels of tyrosine hydroxylase, dopamine and norepinephrine. Nadi NS, et al. **Brain Res** 1981 Jun 1;213(2):365-77

Stimulation of the pituitary-adrenocortical axis and induction of tyrosine hydroxylase by nerve growth factor are not dependent on mouse submaxillary gland isorenin. Otten U, et al. **Brain Res** 1981 Jul 27; 217(1):207-11

Fine structure of the nigrostriatal anlage in fetal rat brain by immunocytochemical localization of tyrosine hydroxylase. Specht LA, et al. **Brain Res** 1981 Aug 10;218(1-2):49-65

Influence of adrenal epinephrine on postnatal development of tyrosine hydroxylase activity in the superior cervical ganglion. Markey KA, et al. **Dev Neurosci** 1981;4(4):267-72

Effects of neonatal ACTH4-10 administration on adult adaptive behavior and brain tyrosine hydroxylase activity. Nyakas C, et al. **Dev Neurosci** 1981;4(3):225-32

Light-microscopic immunocytochemical localization of tyrosine hydroxylase in prenatal rat brain. II. Late ontogeny. Specht LA, et al. **J Comp Neurol** 1981 Jun 20;199(2):255–76

Light-microscopic immunocytochemical localization of tyrosine hydroxylase in prenatal rat brain. I. Early ontogeny. Specht LA, et al. **J Comp Neurol** 1981 Jun 20;199(2):233–53

Importance of fixation in immunohistochemistry: use of formaldehyde solutions at variable pH for the localization of tyrosine hydroxylase. Berod A, et al. **J Histochem Cytochem** 1981 Jul;29(7):844–50

Monovalent cations and striatal tyrosine hydroxylase. Kuczenski R. **J Neurochem** 1981 Sep;37(3):681–6

The immunocytochemical localization of tyrosine hydroxylase within rat sympathetic neurons that release acetylcholine in culture. Higgins D, et al. **J Neurosci** 1981 Feb;1(2):126–31

Striatal tyrosine hydroxylase activity: multiple conformational kinetic oscillators and product concentration frequencies. Mandell AJ, et al. **J Neurosci** 1981 Apr;1(4):380–9

Neuroleptic drugs activate tyrosine hydroxylase of retinal amacrine cells. Cohen J, et al. **J Pharmacol Exp Ther** 1981 Aug;218(2):390–4

Dopaminergic agonist and antagonist effects on striatal tyrosine hydroxylase distribution. Smith CP, et al. **Life Sci** 1981 Jan 12; 28(2):193–7

Effect of estradiol benzoate and clomiphene on tyrosine hydroxylase activity and on luteinizing hormone and prolactin levels in ovariectomized rats. Tobias H, et al. **Life Sci** 1981 Aug 17; 29(7):711–6

Tetrahydrobiopterin increases in adrenal medulla and cortex: a factor in the regulation of tyrosine hydroxylase. Abou-Donia MM, et al. **Proc Natl Acad Sci USA** 1981 May;78(5):2703–6

[Increase in the affinity of hypothalamic tyrosine hydroxylase for tyrosine as a result of the action of dopamine on the synaptosome membrane] Mineeva MF, et al. **Dokl Akad Nauk SSSR** 1981;258(2):501–4 **(Rus)**

VANILMANDELIC ACID

Constructing a normal range [letter] Altman DG. **Clin Chem** 1979 Mar; 25(3):492–3

Determination of vanillylmandelic acid in urine by pre-column dansylation using micro high-performance liquid chromatography with fluorescence detection. Yamada K, et al. **J Chromatogr** 1981 Apr 10; 223(1):176–8

VASOPRESSINS

Barrel rotation induced by vasopressin and involvement of dopaminergic and cholinergic functions in rats. Yamada K, et al. **Arch Int Pharmacodyn Ther** 1981 May;251(1):88–94

Immunocytochemistry of luteinizing hormone-releasing hormone, vasopressin, and corticotropin following deafferentation of the basal hypothalamus of the male rat brain. Scott PM, et al. **Cell Tissue Res** 1981;219(2):393–402

Total circulatory capacity in the rat. Effects of epinephrine and vasopressin on compliance and unstressed volume. Trippodo NC. **Circ Res** 1981 Oct;49(4):923–31

Effect of captopril on cardiovascular, sympathetic and vasopressin responses to hemorrhage. Zerbe RL, et al. **Eur J Pharmacol** 1981 Jul 10;72(4):391–5

Regulation of vasopressin-sensitive adenylate cyclase by calmodulin. Ausiello DA, et al. **J Biol Chem** 1981 Oct 10;256(19):9796–8

Fructose 2,6-bisphosphate. Hormonal regulation and mechanism of its formation in liver. Hue L, et al. **J Biol Chem** 1981 Sep 10; 256(17):8900–3

Vasopressin stimulates release of beta-lipotropin and beta-endorphin in conscious rats as measured by radioimmunoassay of unextracted plasma. Anhut H, et al. **Naunyn Schmiedebergs Arch Pharmacol** 1981 Feb; 316(1):59–63

Water intake inhibition and vasopressin release following intracerebroventricular administration of tachykinins to rats of the Wistar and Brattleboro strain. Cantalamessa F, et al. **Pharmacol Res Commun** 1981 Jul;13(7):641–55

[Effects of GSH on endocrine function and lysosomal enzyme levels during cardiopulmonary bypass in man (author's transl)] Matsuki A, et al. **Masui** 1981 Feb;30(2):150–7 (Eng. Abstr.) **(Jpn)**

VASOTOCIN

Electron-microscopic immunocytochemical demonstration of separate vasotocinergic, mesotocinergic and somatostatinergic neurons in the hypothalamic magnocellular preoptic nucleus of the frog. Van Vossel-Daeninck J, et al. **Cell Tissue Res** 1981;218(1):7–12

VIOLENCE

The psychiatrically violent patient [letter] **Br Med J [Clin Res]** 1981 Apr 11;282(6271):1232

Violence: the ugly face of amphetamine abuse. Siomopoulos V. **IMJ** 1981 Jun;159(6):375–7

VISUAL PERCEPTION

Changes in brain biogenic amines in cats performing a symmetrically reinforced go-nogo visual discrimination task. Kitsikis A, et al. **Behav Neural Biol** 1981 Jun;32(2):133–47

Stimulating effects of amphetamine on the visual system. Andreeva OG, et al. **Hum Physiol** 1980 May-Jun;6(3):199–205

Use of simple tasks to test for impairment of complex skills by a sedative. Ellinwood EH Jr, et al. **Psychopharmacology (Berlin)** 1981; 73(4):350–4

[Role of neuronal and neuropile serotonin in the visual analyzer] Uzbekov MG, et al. **Biull Eksp Biol Med** 1981 Apr;91(4):389–90 (Eng. Abstr.) **(Rus)**

[Effect of psychic stimulants on the temporal parameters of visual perception] Barkov NK, et al. **Farmakol Toksikol** 1981 Jan-Feb; 44(1):12–4 (Eng. Abstr.) **(Rus)**

WAKEFULNESS

Does para-chlorophenylalanine produce disturbed waking, disturbed sleep or activation by ponto-geniculo-occipital waves in cats? Ursin R. **Waking Sleeping** 1980 Jul-Sep;4(3):211-21

☆U.S. GOVERNMENT PRINTING OFFICE: 1982-361-180/102

The *Psychopharmacology Bulletin* is prepared by the Pharmacologic and Somatic Treatments Research Branch of the National Institute of Mental Health. Its purpose is to facilitate the dissemination and exchange of information among the national and international scientific community. The emphasis is on rapid, informal reporting of work which has not appeared in the more formal literature. We invite contributions such as original articles, brief reports, review articles, letters to the Editor, news items, books for review, and announcements appropriate for the *Bulletin*.

All material published in the *Psychopharmacology Bulletin* is in the public domain unless otherwise noted. Publication in the *Bulletin* therefore does not preclude publication elsewhere.

Individuals interested in submitting material to the *Psychopharmacology Bulletin* should contact:

Allen Raskin, Ph.D.
Editor-in-Chief
Psychopharmacology Bulletin
National Institute of Mental Health
5600 Fishers Lane Rm. 10C-14
Rockville, MD 20857

We respectfully ask you to adhere to the following guidelines when preparing a paper for the *Psychopharmacology Bulletin:*

1. Manuscript Format: Manuscripts should be typed double-spaced with ample margins, and submitted in triplicate. Do not split paragraphs from one page to another, even if this makes page lengths uneven. Also, do not hyphenate words at the end of a line, even if this makes uneven lines.

Title page should include each author's name, degree, and full address.

Papers should be written in *third* person, e.g., the investigators found, *Not*: I found, we found. Contents should be *substantive*, not indicative, e.g., the investigator used the gas chromatography method to determine the three molecular structures, *Not*: The author described the method for determining the structure of the drug.

2. Figures: Figures, charts, or graphs should be submitted as glossies (photographs printed on smooth shiny paper) or should be professionally prepared using black ink on white paper. Only one copy is needed. Indicate in the text where these figures and their legends should be placed.

3. References: References mentioned in the text should appear as full citations in the **References** following the text with *all* authors cited in the reference list, e.g., Simpson, G.M., Lee, L.H., Zubok, B, and Gardos. A rating scale for tardive dyskinesia. *Psychopharmacology (Berlin)*, 64(2):171-179, 1979.

If a work has two authors, always cite both names every time the reference occurs in the text, e.g. (Swanson & Cole 1974). If more than two authors, cite only the surname of the first author in the text followed by et al., e.g., Williams et al. 1963.

4. Abbreviations: Abbreviations should appear in parentheses after the first time they are mentioned in the paper, ie., Brief Psychiatric Rating Scale (BPRS).

Use generic names in referring to drugs; trade names may be given in parenthesis the first time a drug is mentioned only.

Journal titles should be abbreviated in the *References* according to the National Library of Medicine's Index Medicus.

5. Brief Reports: Authors wishing very rapid reporting of new work may submit manuscripts of up to five typed double-spaced pages for inclusion as Brief Reports. If accepted, these results would appear in the next issue of the *Bulletin*. In preparing a manuscript for publication as a Brief Report, please follow the format cited above.

The *Psychopharmacology Bulletin* is available on subscription from the Superintendent of Documents, Government Printing Office, Washington, D.C. 20402. Subscription price $11.00 per year for the United States. All other countries add $2.75 for postage. Please make check or money order payable to the Superintendent of Documents. An annual subscription for four quarterly issues begins with the next issue following receipt of the order. Single copies and back issues may also be ordered from the Superintendent of Documents. The expiration date is printed on the top line of the address label. Change of address and complaints about non-receipt of issues should be sent to the Superintendent of Documents, and should include the old address, preferably a mailing label, as well as the new address.

Addendum 1
Meeting Announcements 1

20th Annual Meeting of the ACNP—Abridged Proceedings—

Positron Emission Tomography (PET) and Cortical Localization: Clinical Studies in Psychiatry and Neurology—

Positron Emission Tomographic Studies of Epilepsy, Brain Tumors, and Alzheimer's Disease—*Thomas N. Chase, Rodney A. Brooks, Robert L. DeLaPaz, Alessandro Denaro, Giovanni DiChiro, Reymon Durso, Paul Fedio, Norman L. Foster, Robert M. Kessler, Paul L. Kornblith, Conrad V. Kufta, Ronald G. Manning, Michael E. Newmark, Nicholas J. Patronas, Roger Porter, Sumio Sato, Barry H. Smith, and William H. Theodore* 3
Cerebral Blood Flow in Depression and Mania—*A. John Rush, Michael A. Schlesser, Ernest Stokely, Frederick R. Bonte, and Kenneth Z. Altshuller* 6

Biochemical and Behavioral Studies of Anxiety—

Convulsive Benzodiazepine Receptor Ligands—*Claus Braestrup, Erling N. Petersen, and Mogens Nielsen* 8
Benzodiazepine Receptor: Interaction of a Selective Benzodiazepine Antagonist, Ro 15-1788—*H. Möhler and J. G. Richards* 10

Psychopharmacologic Treatment of Obsessive-Compulsive Disorder—

Clomipramine Treatment of Obsessive Disorder—Biochemical and Clinical Aspects—*Marie Åsberg, Peter Thorén, and Leif Bertilsson* 13

Quo Vadis—Biology of Schizophrenia—

Introductory Comments—*Edward F. Domino* 21
Two Dimensions of Pathology in Schizophrenia: Dopaminergic and Non-Dopaminergic—*Timothy J. Crow* 22
Schizophrenia and Late Maturational Brain Changes in Man—*Irwin Feinberg* 29

Dopamine and the Neural Substrates of Depression—

Evidence in Support of a Role of Dopamine in Affective Illness—*Angelos E. Halaris* 31
Mania, Depression, and Brain Dopamine: An Overview—*Axel Randrup, Ib Munkvad, and Rasmus Fog* 35

Nonlinear Dynamics in Brain Processes—

A Mathematical Model for the Effect of Tetrahydrobiopterin Level on Tyrosine Hydroxylase Kinetic Fluctuations—*Patrick V. Russo* 36
Ordering the Fluctuations of Tryptophan Hydroxylase: Lithium and Chlorimipramine—*Suzanne Knapp* 39
Characterization of Drug Effects on the EEG by Power Spectral Band Time Series Analysis—*Cindy L. Ehlers and James W. Havstad* 43
Variational and Probabilistic Aspects of Exploratory Behavior in Space: Four Stimulant Styles—*Mark A. Geyer* 48
Heart Rate Variational Characteristics in Psychopathology: A Pilot Study—*Michael R. Blackburn* 51

Page

Attending or Discriminating 40 Hz-Modulated Tones Induces Phase-Locked Subharmonic Resonances in the EEG—*Scott D. Makeig and Robert Galambos* 55

Nonlinear Dynamics in Brain Processes—*Arnold J. Mandell* 59

Interaction Among Government, Industry, and Extramural Investigators: New Developments and Problems—

An Investigator's View—*Arthur Rifkin* 64

Industry's Response to New Drug Development—*Victor B. Slotnick* 66

The Balance Sheet (The Other Side of the Ledger)—*Paul Leber* 68

New Biological Approaches to Schizophrenia—

Dopamine Neuronal Instability: A Model for the Schizophreniform Psychoses—*Roy J. King, Joachim D. Raese, Bernard A. Huberman, and Jack D. Barchas* 70

Retinal Oscillatory Potentials in Schizophrenia: Implications for the Assessment of Dopamine Transmission in Man—*Joachim D. Raese, Roy J. King, Debbie Barnes, Philip A. Berger, Jack D. Barchas, Michael Marmor, and Peggy Hock* 72

A Convergence of Findings in the Psychophysiology of Schizophrenia—*Walton T. Roth and Jared R. Tinklenberg* 78

What Is Vital Depression (Endogenous Depression or Melancholia), and How Can It Be Reliably Assessed?—

Pituitary-Adrenal Assessment in Identifying Subtypes of Depression—*Walter Armin Brown and C. Brandon Qualls* 84

Benzodiazepine Abuse: What Are the Data?—

Subjective Effects of Benzodiazepines and Methaqualone in Recreational Sedative Users—*Jonathan O. Cole, Maressa Hecht Orzack, Francine M. Benes, Barbara J. Beake, Michael P. Bird, Yoram Bar Tel, and Martin Ionescu-Pioggia* 87

What Is the Effect of "Stress" on Neuroendocrine Function? In-Depth Consideration of Recent Theorizing—

Heterogeneity in the Response Pattern of Organ Systems to Stress: Mediators and Mechanisms—*Cynthia M. Kuhn, Alberto Grignolo, Mark Johnson, and Saul M. Schanberg* 96

Neurotransmitter Receptors: Heterogeneity, Regulation, and Function—

Correlation Between Pharmacological Activity and the Influence of GABA on the Binding of Flunitrazepam and the Specific Benzodiazepine Antagonist, Ro 15-1788—*Frederick J. Ehlert, William R. Roeske, Andrew Chen, and Henry I. Yamamura* 100

Down Regulation and Heterogeneity of Opiate Receptors—*Kwen-Jen Chang and Steven G. Blanchard* 102

Alpha Adrenergic Receptor Subtypes: Physiological Relationships and Mechanisms—*Brian B. Hoffman* 107

Psychobiology of Premenstrual Change—

Retrospective Report of Premenstrual Depressive Changes: Factors Affecting Confirmation by Daily Ratings—*Jean Endicott and Uriel Halbreich* 109

Premenstrual Tension in Biochemical and Psychotropic Drug Assessment—*Richard I. Shader and Jerold S. Harmatz* 113

Future Directions in the Study of Premenstrual Changes—*Uriel Halbreich and Jean Endicott* 121

Page

Child Psychopharmacology—

Methylphenidate in Adults with MBD Symptomatology—*Jeffrey A. Mattes, Lane Boswell, and Herman Oliver* 124
Lithium and Haloperidol in Hospitalized Aggressive Children—*Magda Campbell, Arthur M. Small, Wayne H. Green, Susan J. Jennings, Richard Perry, Walter G. Bennett, Maria Padron-Gayol, and Lillian Anderson* 126

Monoamine Receptor Sensitivity and the Mechanism of Action of Antidepressant Treatment—

The Monoamine Receptor Sensitivity Hypothesis of Antidepressant Drug Action—*George R. Heninger and Dennis S. Charney* 130
Catecholamine-Stimulated Production of Melantonin After Administration of Antidepressants—*William E. Heydorn, Stanley Caroff, and Alan Frazer* 135
Agonist-Induced Changes in Behavior as a Measure of Functional Changes in Receptor Sensitivity Following Chronic Antidepressant Treatments—*Michael Davis* 137
Antidepressant Treatment and Central Adrenergic and Histamine Receptors—*Ghanshyam N. Pandey, P. Sudershan, and John M. Davis* 147
Assessment of Adrenergic and Serotonergic Receptor Function: Implications for the Etiology and Treatment of Depression—*Dennis S. Charney and George R. Heninger* 151

Protein Phosphorylation and Synaptic Mechanisms—

Introductory Comments—*Walter Lovenberg* 156
The Possible Role of Phosphorylation of Tyrosine Hydroxylase in Catecholaminergic Neurons—*Mitchell A. Lazar and Jack D. Barchas* 157
Calcium-Dependent Phosphorylation and the Regulation of Serotonin Synthesis—*Donald M. Kuhn* 161
Control of Phosphorylation of a Vesicle-Associated Protein, Synapsin I—*Mary B. Kennedy* 165

The Indole Hallucinogens—A New Look at Their Mechanisms of Action—

Action of Hallucinogenic Drugs at Postsynaptic Serotonergic Receptors—*Barry L. Jacobs, James Heym, and Kurt Rasmussen* 168
Interaction of Monoamine Blocking Agents with Behavioral Effects of N,N-Dimethyltryptamine—*David M. Stoff, Dilip V. Jeste, Egidio A. Moja, Ken A. Stauderman, and Richard J. Wyatt* 173
Evidence for Opioids as Partial Antagonists for Indole Hallucinogens—*Edward F. Domino and Diane M. Ruffing* 175
In Vitro Models to Examine Regulation of Transmitter Content and Adenylatecyclase Coupled Receptors in Neurons—*David C. U'Prichard, Karen M. Braas, and Deborah J. Kahn* 180

Mental Illness in Pregnancy and the Puerperium—

Model Utility in Postpartum Psychosis—*James A. Hamilton* 184
Hormonal Modulation of Central Dopamine Receptor Sensitivity in the Postpartum Period—*Umberto Scapagnini, Filippo Drago, Ferdinando Nicoletti, Francesco Patti, Mario Matera, and Pier L. Canonico* 187

Membrane Lipids in Neuropsychiatric Disorders—

Membrane Abnormalities in Schizophrenia—*Robert Hitzemann and David Garver* 190
Phospholipids and Phospholipid Methylation in Platelets and Brain—*Donna Mandio Cordasco, David Wazer, David J. Segarnick, Andrew Lautin, Arnold Lippa, and John Rotrosen* . . . 193

Page

Occurrence and Significance of Beta-Carbolines and Tetrahydroisoquinolines—

Cellular Actions and Localization of Beta-Carbolines and Tetrahydroisoquinolines—*Floyd E. Bloom and Jack D. Barchas* 198

Endogenous Opioid Mechanism in Neuroendocrine Regulation in Normal and Psychopathological States—

The Effect of a Methadone Challenge on the Prolactin and Growth Hormone Responses of Psychiatric Patients and Normal Controls—*Lewis L. Judd, S. Craig Risch, Donal C. Parker, David S. Janowsky, David S. Segal, and Leighton Y. Huey* 204

Response of Plasma Cortisol and β-Endorphin Immunoreactivity to Surgical Stress—*David Pickar, Martin R. Cohen, Michel Dubois, and William E. Bunney, Jr.* 208

Elevated Plasma β-Endorphin Concentrations in Depression and Cholinergically Supersensitive Release Mechanisms—*S. Craig Risch, David S. Janowsky, Lewis L. Judd, and Leighton Y. Huey* 211

Endorphins May Be Involved in the Behavioral Response to Dextro-Amphetamine—*Uriel Halbreich, Susanna Goldstein, Ee-Sing Lo, and Jean Endicott* 216

Where Is the "Lesion" in Patients Who Fail to Suppress Plasma Cortisol Concentrations with Dexamethasone?—*Ned H. Kalin, Stephen J. Weiler, William T. McKinney, Gary W. Kraemer, and Steven E. Shelton* 219

The Epidemiology of Mental Disorders: Results from the Epidemiologic Catchment Area Study (ECA)—

An Epidemiologic Perspective on Senile Dementia—Facts and Fragments—*Jacob A. Brody and Lon R. White* 222

Workshop—

Antipsychotics and Clinical Response: An Overview—*John M. Davis, Katherin Hendricks, and Javaid I. Javaid* 225

Measurement of Antipsychotics in Patients—*Javaid I. Javaid, Robert D. Linden, and John M. Davis* 227

ADDENDUM

The October 1981 issue of the *Psychopharmacology Bulletin* (Vol. 17, No. 4, p. 9) included a report on the Clinical Research Center at the Western Psychiatric Institute and Clinic (WPIC) of the University of Pittsburgh Medical School. This report did not include a full description of one of the projects at WPIC, the National Institute of Mental Health (NIMH) Treatment of Depression Collaborative Research Program. This program was initiated and designed by the staff of the NIMH Psychosocial Treatments Research Branch. The program is funded by Cooperative Agreements with the Psychosocial Treatments Research Branch and continues to be coordinated by NIMH staff. The collaborating research sites, in addition to the University of Pittsburgh, include the University of Oklahoma and George Washington University. Three sites are involved in training therapists for the program, Yale University, the University of Western Ontario, and Rush Presbyterian St. Luke's Medical Center. Also collaborating in data management and analysis aspects of the program is the Perry Point Veterans Administration Cooperative Studies Program.

Meeting Announcements

The Brazilian Geriatrics and Gerontology Society (SBGG) will hold its 6th Congress in Belo Horizonte (Minas Gerais), Brazil on October 17-22, 1982. The SBGG is the only scientific and philanthropic society in Brazil carrying out programs for the elderly population. The congress is open to all people involved in the care of the elderly. There will be lectures, debates, and discussions on subjects in the area of geriatrics and basic and social gerontology. Contact Flavio Aluizio Xavier Cancado, Head of the SBGG, Palacio das Artes, Belo Horizonte, MG, Brazil.

* * * *

The 4th Congress of the Latin-American Federation of Geriatrics and Gerontology Societies will be held in Montevideo, Uruguay on October 24-28, 1982.

* * * *

20th Annual Meeting of the ACNP — Abridged Proceedings

The Twentieth Annual Meeting of the American College of Neuropsychopharmacology (ACNP) was held in Coronado, California on December 16-18, 1981.

This Meeting annually brings together investigators actively involved in psychopharmacologic research. The papers presented at the sessions are indicative of the state-of the-art in psychopharmacology in the United States, as well as in some foreign countries.

For those who did not attend the conference, we are again publishing summaries of the presentations given at various sessions. In some cases, not all of the papers were included because they were not received in time. Papers based on poster sessions will be published in Vol. 18, No. 4, October 1982 issue.

Publication of these summaries in the *Bulletin* does not prejudice later publication of the full papers elsewhere.

Clinical measurements of local rates of glucose metabolism provide an important new approach to the non-invasive study of human central nervous system function. This procedure, adapted from a model developed by Sokoloff and coworkers (Sokoloff et al. 1977) involves the intravenous administration of 18F-2-fluoro-2-deoxy-D-glucose (FDG) whose phosphorylated metabolite accumulates in brain cells in proportion to their rate of glucose utilization (Reivich et al. 1977; Phelps et al. 1977; Reivich et al. 1979). A positron emission tomography (PET) scanner provides maps of the regional concentration of the radioactively labeled tracer throughout the brain (Ter-Pogossian et al. 1975; Kuhl et al. 1977; Phelps et al. 1978). Since the local metabolic rate for glucose appears to correlate with neuronal firing rates (Sokoloff 1980) as well as with several aspects of normal brain function (Greenberg et al. 1981; Huang et al. 1980; Phelps et al. 1979, 1981), the FDG technique may contribute substantially to the study of neurologic disease. Recent observations by the National Institute of Neurological and Communicative Disorders and Stroke (NINCDS) investigators of patients with epilepsy, brain tumors, and Alzheimer's disease will be briefly reviewed.

Method

Consenting individuals were admitted to the National Institutes of Health (NIH) Clinical Center for study. FDG was prepared (Ido et al. 1980), with 18F obtained from the Naval Research Center or Brookhaven National Laboratory as previously described (DiChiro et al., submitted). By means of bilateral upper extremity catheters, up to 5 mCi of FDG was rapidly injected intravenously while serial "arterialized" venous blood samples were obtained from the opposite extremity for the determination of FDG and glucose concentrations. Following isotope administration, patients were kept quietly in the recumbent position to minimize external stimuli. PET scans were performed by an Ortec ECAT II tomograph having a spatial resolution of approximately 1.7 cm in the image plane and 1.8 cm in the axial direction. Scanning, usually at 6 sequential levels parallel to the canthomeatal plane, began about 30 minutes after FDG infusion. Calculation of local metabolic rates for glucose in mg per 100g of tissue per minute (Huang et al. 1980; DiChiro et al., submitted) was based on rate constants determined from normal young adults. In some studies comparisons were made between the metabolic rate for glucose in selected brain regions and corresponding contralateral zones.

Epilepsy

PET scanning following FDG adminstration helps identify local alterations in cerebral function in patients with complex partial seizures (Newmark et al. 1981). Previous studies using this method suggested that individuals with focal seizures, when studied interictally, evidenced a region of reduced glucose metabolism that becomes hypermetabolic during a clinical seizure (Kuhl et al. 1980). Subsequent NINCDS investigations have sought to ascertain the usefulness of the FDG technique in patients with diffuse, nonlocalized epileptiform foci, as well as to determine the stability of PET abnormalities in response to changes in various environmental factors.

All study subjects had refractory complex partial seizures associated with normal neurologic examinations and computed transmission tomographic (CT) scans. Interictal PET scans in patients with unilateral or predominantly unilateral epileptiform discharges invariably revealed an area of hypometabolism. Moreover, three of the four patients studied who had diffuse or bilateral discharges had a discernible interictal hypometabolic focus.

PET results were substantially influenced by clinical seizures occurring shortly after FDG injection. Individuals with seizures during the 30-minute period of FDG uptake were found to have a hypermetabolic focus in the area that was hypometabolic interictally. A comparison of interictal and ictal scans in such patients allowed a substantially better localization of the seizure focus than either ictal or interictal scans alone. Interictal PET foci did not, however, appear to be affected by the frequency of seizures between scans or the frequency of spike discharges occurring during the 30 minutes following FDG injection. Changes in anticonvulsant medication also failed to modify PET scan results. Similarly, alterations in the patient's state of alertness had no discernible effect on interictal PET abnormalities.

Brain Tumors

Human brain tumors range in malignancy from slow growing, relatively benign lesions (e.g., Grade I or II astrocytomas) to rapidly expanding, highly invasive neoplasms (e.g., glioblastomas). Although current radiologic techniques often provide useful information, diagnostic uncertainties with respect to tumor grade are not uncommon. Moreover, assessment of tumor recurrence after surgical, radiologic, or chemotherapeutic intervention may be difficult. Since available evidence suggests a positive correlation may exist between degree of malignancy and rate of tumor glycolysis (Macbeth & Bekesi 1962; Wolleman 1972), the FDG-PET technique for quantifying local rates of glucose metabolism may afford a more accurate, noninvasive approach to the clinical evaluation of cerebral neoplasms (DiChiro et al., submitted)

NINCDS studies of over 20 patients with primary brain tumors now indicate that a positive correlation does exist between malignancy grade and metabolic rate as determined by the FDG method (DiChiro et al., submitted). On average, Grade III and IV tumors exhibit twice the metabolic rate of the more benign Grade I and II tumors. It now also appears that clinically successful chemotherapeutic or radiologic treatment may be associated with a reduction in the apparent glucose utilization of these tumors.

Alzheimer's Disease

PET evaluations of patients with Alzheimer's disease may eventually provide insight into the pathophysiology of neuronal degenerative disorders as well as into the localization of major human brain functions (Ferris et al.1980; Foster et al. 1982). Right-handed Alzheimer's disease patients with disproportionate failure of visuoconstructive, language, or memory function were selected for initial study (Foster et al. 1982). CT scans from four individuals in whom constructional apraxia was the predominant cognitive impairment revealed diffuse cortical atrophy without focal abnormalities. PET scans of these patients consistently showed a conspicuous focus of low glucose consumption in the right parietal region. Glucose metabolism in this area of the nondominant hemisphere, classically associated with constructional praxis, averaged 24 percent less than the same region in the opposite hemisphere. This right-left difference significantly correlated with various tests of visuoconstructive function (e.g., Rey copy test, block design). Stimulation of one apractic patient by repetitive spatial tasks during the 30-minute period immediately following FDG injection failed to produce a significant increase in the metabolic rate of this area of hypofunction.

Focal right parietal hypofunction was not found on PET scans from Alzheimer's disease patients who were free of clinically significant constructional apraxia. On the other hand, a patient with global receptive and expressive aphasia out of proportion to his other cognitive deficits had a conspicuous focal area of hypometabolism in the left parietal region. This finding was hardly unanticipated, in view of the well-accepted brain localization of language function as well as the results of a previous PET study of aphasic patients (Metter et al. 1981). Considering the entire group of nine Alzheimer's disease patients studied thus far, there was a significant positive correlation between degree of language impairment (as evidenced by tests such as the verbal IQ on the Wechsler Adult Intelligence Scale) and absolute left temporal-parietal metabolism or relative left temporal-parietal reduction compared with the same area in the right hemisphere. Four Alzheimer's patients, clinically selected prior to PET scanning on the basis of disproportionate failure of memory, had no significant left-right differences in the temporal-parietal regions which are classically associated with aphasic disturbances. On the other hand, temporal lobe glucose metabolism, especially medially in the hippocampal area, tended to be reduced bilaterally in these individuals compared with other cortical regions or with the hippocampal regions in Alzheimer's disease patients with predominant apractic or aphasic dysfunction.

Concluding Remarks

Results are briefly presented from three ongoing NINCDS studies of neurologic disorders in which the application of the FDG-PET technique now appears exceptionally promising, not only in relation to direct patient management but also to the broad study of normal and disordered human brain function. Conclusions based on the present limited material must remain highly tentative, especially in view of the relatively poor spatial resolution of available scanning equipment, the lack of appropriate normative data, and the uncertain applicability of some assumptions used in the calculation of metabolic rates. Considering the pace of current investigative efforts, it can be confidently predicted that these limitations will appreciably lessen in the near future. Use of other positron-labeled tracers, alone or in combination with FDG, will further enhance the ultimate clinical usefulness of the PET technique.

Cerebral Blood Flow in Depression and Mania[1]

A. John Rush, M.D.,[2] Michael A. Schlesser, M.D.,[2] Ernest Stokely, Ph.D.,[3] Frederick R. Bonte, M.D.,[3] and Kenneth Z. Altshuller, M.D.[2]

Various investigations suggest patients with affective disorders suffer impairment of higher cortical functions (Ross & Rush 1981). Measures of regional cerebral blood flow (rCBF) provide methods that may potentially tell us, albeit indirectly, about the functional activity and/or capacity of specific regions in the brain. Until recently, such measures were restricted to information derived from lateral views of both hemispheres. Stokely et al. (1980) have developed a single photon emission tomograph method using inhaled 133 Xenon gas that provides views of three cross-sectional brain slices (4 cm apart) with a resolution of 1.7 cm (Lassen et al. 1981).

Twenty-six adult male and female patients, aged 19-69, were evaluated with Research Diagnostic Criteria (Spitzer, Endicott, & Robins 1978), Diagnostic and Statistical Manual-III (DSM-III) (APA 1980), and the 1 mg Dexamethasone Suppression Test (DST) (Carroll et al. 1981). Whenever feasible, subjects ($N = 17$) were studied at two points in time (when acutely ill and later when in clinical remission). Symptom severity was gauged by the 17-item Hamilton Rating Scale for Depression (HRS-D) (Hamilton 1960). Treatment varied across subjects and included electroconvulsive therapy (ECT), tricyclic antidepressants, alprazolam, monoamine oxidase inhibitors (MAOIs), lithium, or haloperidol. Treatment was ongoing when the repeat measurement of rCBF was made for those taking medication. For those receiving ECT, no less than 2, and most typically 5 days, elapsed between the last ECT treatment and the second rCBF determination. Treatment selection was independent of rCBF findings.

RCBF in ml/100 gm/min was determined using a single photon emission computerized tomographic scanner (Stokely et al. 1980). Values reported were derived from the mid slice for both whole brain and/or right and left hemisphere values separately. The algorithm used to calculate flow is still undergoing revision; thus, the actual numbers shown likely exceed actual flow in all subjects. However, the same algorithm was used in all subjects, so that comparisons between subject groups and within subjects over time are likely to be valid. Controls were gathered from volunteers at the medical center who reported themselves to be free of psychiatric symptomatology, medical illnesses, and medications.

Results

Ten unipolar depressed subjects who were both endogenous by RDC and melancholic by DSM-III were studied (UP-ED). Six Bipolar I or II subjects in the depressed phase (BP-D); four nonendogenous, nonmelancholic, unipolar patients (UP-NED); and six Bipolar I patients in mixed or manic phases (BP-MM) were studied.

RCBF was lower for the UP-ED group ($t = 2.10$, $p < .05$) and higher for the BP-MM group ($t = 2.97$, $p < .01$) compared to controls. The BP-D group did not differ from controls ($t = 0.09$, $p < .50$). Flow in UP-NED patients was higher than controls, although the sample size precludes meaningful statistical evaluation.

A significant *increase* in whole brain rCBF ($N = 8$) was found with treatment and complete clinical response (HRS-D score of 6 or less) in the UP-ED group (paired *t*-test, $t = 2.62$, $p < .04$). The type of treatment (ECT vs. medication) did not relate to this finding.

RCBF changes in treated BP-D patients were more heterogenous (three showing increases and three with decreases in whole brain rCBF). Two of the three with decreases subsequently relapsed in the following 2 months. No significant pre- or posttreatment differences for the groups as a whole were found (paired *t*-test, $t = -9.546$, $p < .65$).

Taken together, these data suggest that a) whole brain cerebral blood flow is low in melancholic, endogenous UP patients compared to controls and compared to themselves when later clinical remission; and b) whole brain cerebral blood flow is elevated in BP-MM patients compared to controls. To determine the differential contribution of the left and right hemispheres to these findings, flow rates for each hemisphere, as seen from the mid-slice, were calculated. The increases or decreases in whole brain rCBF found in the above diagnostic groups profoundly involved *both* left and right hemispheres.

While the majority of controls (14/16) showed a very slightly greater flow to the right hemisphere when at rest with eyes open, the majority of all UP-ED, BP-MM, and BP-D patients (13/22) showed a slightly greater flow on the left when acutely ill. This was significantly different from normals by chi-square ($X^2 = 7.26$, $p < .01$).

While both between-group and within-subject comparisons for UP-ED patients suggest that a lower rCBF is found during this illness and between-group comparisons suggest a higher rCBF in BP-MM and a lower rCBF in UP-ED patients, these findings are only preliminary. Samples are small; flow computations are still under investigation; more extensive control data are needed; better controls for age effect and Pa CO_2 are needed; and the effect of medications on rCBF deserves closer scrutiny.

One group (Risberg 1980) suggests no differences between depressed and controls, whereas another group (Matthews et al. 1980) did find a lower left hemisphere flow in their depressed subjects and a trend toward lower right hemisphere flow. While these data demonstrate the feasibility of rCBF determinations by inhaled 133-Xenon, the findings must be replicated.

Convulsive Benzodiazepine Receptor Ligands

Claus Braestrup, M.D.,[1] Erling N. Petersen, Ph.D.,[2] and Mogens Nielsen, Ph.D.[1]

It is generally believed that the benzodiazepine group of minor tranquilizers exert their pharmacological and clinical effects by an interaction with specific benzodiazepine (BZ) receptors located on neurons in the central nervous system (CNS) (Braestrup & Squires 1978).

It was believed that agents that interacted with benzodiazepine receptors would have benzodiazepine-like pharmacological effects. Recently, however, it was observed that the very potent BZ receptor ligand ethyl β-carboline-3-carboxylate (β-CCE) (Braestrup et al. 1980) failed to elicit benzodiazepine-like actions but that β-CCE, on the other hand, antagonized effects of benzodiazepines (Tenen & Hirsch 1980; Cowen et al. 1981). More recently, an imidazodiazepine carboxylic acid ethyl ester has been described (Ro 15-1788) which also antagonizes the effects of benzodiazepines (Hunkeler et al. 1981). These findings indicate that BZ receptor ligands bind in different ways to BZ receptors. Thus ligands may have different efficacies without differences in affinity.

During structural modifications of β-CCE we observed that the corresponding methyl ester, β-CCM [10-50 mg/kg intraperitoneally (i.p.)] and, in particular, methyl 4-ethyl-6, 7-dimethoxy-β-carboline-3-carboxylate (DMCM, Figure) (5-15 mg/kg, i.p.) produced convulsions in mice and rats when given i.p. Convulsions produced by DMCM (15 mg/kg, i.p.) were similar in quality to convulsions produced by bicuculline and pentylenetetrazol.

Convulsions produced by β-CCM and DMCM

DMCM

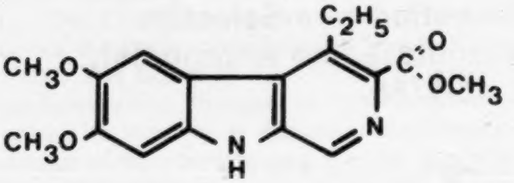

FIGURE. Chemical Structure of DMCM (methyl 4-ethyl-6, 7-demethoxy-β-carboline-3-carboxylate; ZK 90798)

are probably the consequence of BZ receptor interaction for reasons cited below:

1. β-CCM and DMCM have high affinity in vitro for BZ receptors, IC50 values for inhibition of specific [^{3}H]-flunitrazepam (^{3}H-FNM) binding to rat cerebellar membranes are 3 nM and 11 nM, respectively.

2. β-CCM and DMCM occupy BZ receptors in the brain of living animals after systemic administration. The dose that inhibits by 50 percent the BZ binding sites available for [^{3}H]-FNM intraventricularly) (i.v.) is 22 mg/kg (i.p., 35 min) for β-CCM and 4 mg/kg (i.p., 35 min) for DMCM in mouse forebrain.

3. The occurrence of clonic convulsions, tonic convulsions, and death, produced by 15 mg/kg, i.p., of DMCM in mice, can be antagonized by β-CCE (70 mg/kg, i.p.) and Ro 15-1788 [7 mg/kg, orally (p.o.)]. These agents are *not* general anticonvulsants but share the ability to occupy BZ receptors without producing overt pharmacological actions when given alone. Barbiturates and benzodiazepines likewise inhibit convulsions produced by DMCM.

4. Alternative mechanisms of action of β-CCM and DMCM have not been suggested by pharmacological and biochemical studies. When investigated with affinity binding techniques *in vitro*, DMCM, for example, does not interact with serotonin, dopamine (D-2), noradrenaline (α_1), gamma aminobutyric acid (GABA), glutamate, opiate (μ), or cholinergic (muscarinic) receptors.

5. GABA and BZ receptors are functionally coupled at the molecular level. It has been suggested that the effect of GABA agonist on the affinity of a particular BZ receptor ligand for BZ receptors may reflect the pharmacological profile of that agent (Ehlert et al. 1981; Braestrup & Nielsen 1981; Möhler & Richards 1981). Thus, GABA enhances the affinity *in vitro* of one group of BZ ligands, which consists mainly of conventional benzodiazepines (Group I) and this group of ligands exert benzodiazepine like anticonvulsant and anxiolytic activity in animals and man. For ligands in Group II, GABA has no major effect on the affinity of the ligands for BZ receptors, and members of this group antagonize effects exerted via BZ receptors without having overt pharmacological effects when given alone (examples are several β-carbolines and Ro 15-1788). In Group III, GABA agonists reduce the affinity of the ligands for BZ receptors and ligands in this group. For example β-CCM and, in particular, DMCM, have pharmacological effects opposite to those of the benzodiazepines. Thus, β-CCM and DMCM produce convulsions in rats and mice and in addition produce effects in rats that may be interpreted as anxiogenic (Petersen et al., submitted).

The affinity of DMCM for cerebellar BZ$_1$ receptors *in vitro* in chloride-containing buffer is reduced to 50 percent of the normal value by adding the GABA agonist muscimol (10^{-5}M) to the assay; this effect of muscimol is antagonized by bicuculline (10^{-5}M). The convulsant effect of DMCM and β-CCM is consistent with the BZ receptor/GABA receptor model. Consonant with these conjectures, it has also been observed that DMCM reduces the electrophysiological effects of GABA in cultured spinal neurons from the mouse (J. Lambert, unpublished).

In conclusion, BZ receptor ligands can be divided into at least three groups relating to the coupling between BZ receptors and GABA receptors. Further subclassification according to a chloride channel coupling has also been proposed (Fujimoto et al. 1982). Probably, the BZ receptor can exist in at least two conformations. It was surmised that when Group I ligands bind to the resting state of the receptor, they install a shift in direction of one particular conformational state of the receptor. This new state of the receptor-ligand complex is permissible for chloride channel opening by GABA receptor stimulation. No conformational shift occurs when Group II ligands bind to the receptor. Thus, binding has no overt consequences other than inhibiting access of Groups I and III ligands to receptors. When Group III ligands bind, the receptor attains yet a new conformation which now is inhibitory for chloride channel opening by GABA (GABAergic transmission is reduced). It is not known whether these two assumedly distinct conformations of BZ receptor exist in equilibrium under normal physiological conditions, or whether the resting state of the receptor, found in normal, undrugged individuals, represents a third conformational state.

It should be noted that the experiments described above were conducted using rat cerebellar membranes. Cerebellum is known only to contain one class of BZ receptors, BZ_1 receptors. The present considerations are not related to a BZ_1/BZ_2 receptor subclassification.

Benzodiazepine Receptor: Interaction of a Selective Benzodiazepine Antagonist, Ro 15-1788

H. Möhler, Ph.D.,[1] and J.G. Richards, Ph.D.[1]

Introduction

Recently, Ro 15-1788, a representative of a novel series of imidazodiazepines, was found to selectively antagonize all major central actions of benzodiazepines by competitive high affinity interaction with benzodiazepine receptors in the central nervous system (Hunkeler et al. 1981). Ro 15-1788 itself is not pharmaceutically active in doses sufficient to antagonize benzodiazepine actions in animals and man (Darragh et al. 1981; Haefely et al. 1982; Hunkeler et al. 1981; Möhler et al. 1981; Polc et al. 1981). Ro 15-1788 may find therapeutic application as an antidote in cases of intoxication involving overdoses of benzodiazepines, and in anaethesiology for terminating benzodiazepine-induced sedation (Haefely et al. 1982, Hunkeler et al. 1981).

Difference in Receptor Interaction of Benzodiazepine Agonists and Ro 15-1788

Benzodiazepines and the antagonist Ro 15-1788 interact with the same benzodiazepine receptor sites (Möhler & Richards 1981) as shown, for example, by light-microscopic autoradiography (Figure 1). The mode of receptor interaction, however, must be different, since benzodiazepine agonists trigger a biological response while Ro 15-1788 does not. This different receptor interaction is reflected in the different susceptibility of agonists and antagonists to conformational changes of the benzodiazepine receptor. It is known that, *in vitro,* GABA and some other compounds can alter the affinity of the

---

benzodiazepine receptors for agonists. The affinity of Ro 15-1788, however, remained unchanged under the same conditions (Möhler & Richards 1981). The failure of Ro 15-1788 to respond to conformational changes of the receptor may reflect its inability to induce a conformational change of the receptor and thereby to trigger a biological response.

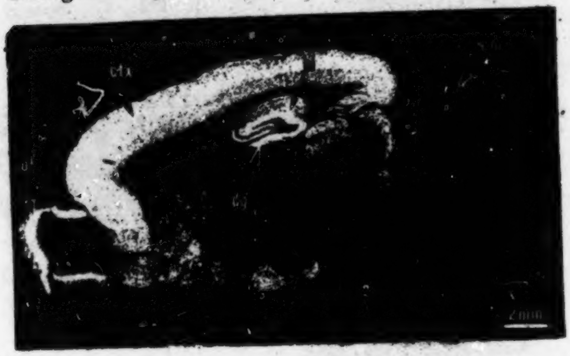

FIGURE 1. Autoradiogram of high affinity binding sites of ^{3}H-Ro 15-1788 in a sagittal section of rat brain. The slide-mounted cryostat section was incubated with 1 nmol·l^{-1} of the radioligand for 40 min at 4°C, washed, rapidly dried and then exposed to LKB Ultrofilm® for 14 days at 4°C. White areas correspond to the presence of the radioligand. Note the high density of binding sites in several brain regions, e.g. olfactory bulb (ol, external plexiform and glomerular layers), cerebral cortex (ctx, particularly layer IV), molecular layers of hippocampus (hi), dentate gyrus (dg), and cerebellum (cm). The same distribution pattern was found when the benzodiazepine agonist ^{3}H-clonazepam was used as radioligand.

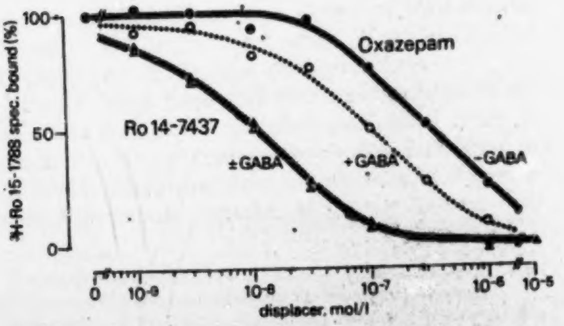

FIGURE 2. ^{3}H-Ro 15-1788 binding in the presence (open symbols) and absence (solid symbols) of 100 μmol·l^{-1} GABA: Inhibition by the agonist oxazepam (circles) and the benzodiazepine antagonist Ro 14-7437 (triangles).

The different receptor interaction of agonists and Ro 15-1788 *in vitro* can be used as a test to distinguish benzodiazepine agonists from antagonists (Möhler & Richards 1981). Their IC_{50} values are determined in ^{3}H-Ro 15-1788 binding in the presence and absence of 100μm .1^{-1} GABA. For agonists but not antagonists, the IC_{50} value in ^{3}H-Ro 15-1788 binding is reduced in the presence of GABA (Figure 2 and Table). For methyl-β-carboline-3-carboxylate, a convulsant benzodiazepine antagonist, the IC_{50} value was even increased in the presence of GABA (Table).

Table

The Inhibitory Potency (IC_{50}) of Various Benzodiazepine Receptor Agonists and Antagonists in ^{3}H-Ro 15-1788 Binding Tested in the Absence and Presence of GABA

	IC_{50}-ratio ± SEM
Agonists	
Flunitrazepam	2.7 ± 0.3
Diazepam	2.9 ± 0.1
Oxazepam	2.7 ± 0.2
Zopiclone	1.6 ± 0.1
CL 118 872	1.6 ± 0.1
Antagonists	
Ro 15-1788	1.0 ± 0.1
Ro 14-7437	0.9 ± 0.1
Propyl-βCC*	1.0 ± 0.1
Methyl-βCC*	0.6 ± 0.05

*β-carboline-3-carboxylate

According to the different types of response to the presence of GABA, several states of the benzodiazepine receptor may be distinguished: The agonist state characterized by an enhancement of the receptor affinity by GABA, the antagonist state in which the affinity remains unaffected by GABA, and an antagonist/convulsant state in which the affinity of the receptor is reduced by GABA.

Model of Ligand-Receptor Interaction

Based mainly on thermodynamic data, a two-step model of ligand receptor interaction was proposed for benzodiazepine receptors (Möhler & Richards 1981),

$$\begin{array}{l} L + R \overset{1}{\rightleftharpoons} LR \overset{2}{\rightleftharpoons} LR' \\ \qquad\qquad\qquad\; \overset{3}{\rightleftharpoons} LR'' \end{array}$$

in which L is the ligand and R the receptor. Agonists and antagonists participate in reaction (1). Due to their structural properties, agonists but not antagonists can participate in reaction (2) by inducing a conformational change of the receptor to an activated state R′, a prerequisite for the initiation of the agonist drug response. Convulsant receptor ligands induce different conformational change of the receptor reaction (3). Effects opposite to those of benzodiazepine agonists are triggered by these compounds.

Clomipramine Treatment of Obsessive Disorder—Biochemical and Clinical Aspects[1]

Marie Åsberg, M.D.,[2] Peter Thorén, M.D.,[3] and Leif Bertilsson, M.D.[2]

Chronic obsessive-compulsive disorder, a crippling illness in its more severe form, socially disruptive and connected with intense suffering, has long been conceived of as one of the most treatment-resistant conditions known to psychiatry (Goodwin et al. 1969). It is therefore encouraging that a range of new treatments has recently been reported to be effective. Exposure treatment, a variety of behavior therapy, has thus been found to be superior to relaxation procedures (used as a placebo control) in controlled trials (Marks et al. 1980). Among the drugs claimed to be effective are the monoaminoxidase inhibitors (MAOIs), high doses of imipramine (Freed et al. 1972), tryptophan (Yaryura-Tobias & Bhavagan 1977), and clomipramine.

These drugs have different mechanisms of action, but they have one pharmacological effect in common: they potentiate serotonin functions in the brain. Clomipramine, for instance, is the most potent serotonin uptake inhibitor among the tricyclic antidepressants (Carlsson et al. 1969). The MAOIs inhibit enzymatic degradation of serotonin. The serotonin precursor, tryptophan, accelerates synthesis of the transmitter.

These drugs also have (or are claimed to have) antidepressant properties. The tricyclics and the MAOIs have long been used as antidepressants, while tryptophan has been found to potentiate the effect of other antidepressant treatments such as the MAOIs (Coppen et al. 1963), clomipramine (Wålinder et al. 1976), and electroconvulsive therapy (ECT) (d'Elia et al. 1977) in controlled trials.

This pattern of effects raises a number of questions. Is the antiobsessive effect (if any) related to the drugs' effect on serotonin neurons? Is it secondary to amelioration of depression in the obsessive-compulsive patients? What is the relationship between depression and obsessive-compulsive disorder? A close connection between depression and obsessive-compulsive disorder has been recognized since at least the turn of the century (Gadelius 1896). Is obsessive-compulsive disorder merely a variety of depression or are the two disorders different manifestations of a common underlying biochemical abnormality?

As yet, there are not sufficient research data to answer any of these questions, but there is some suggestive evidence which will be discussed in this paper. To the authors' knowledge, placebo-controlled trials have only been published with clomipramine, and the discussion will therefore be limited to studies of this drug.

The Controlled Trials

In 1980, three double-blind, placebo-controlled clinical trials of clomipramine in obsessive-compulsive disorder were published. Although their designs differed, they complemented each other in a number of ways.

Thorén et al. (1980a) studied antiobsessive effects in 24 hospitalized patients with severe, chronic (median duration 11 years) obsessive-compulsive disorder. After a drug-free "washout" period, the patients were randomly allocated to one of three treatment groups, clomipramine (150 mg/day divided in three doses), nortriptyline (150 mg/day), or placebo. Treatment was continued on a fixed dosage for 5 weeks. With the exception of occasional low doses of benzodiazepines, no concomitant drug treatment was allowed.

All patients met Research Diagnostic Criteria (RDC) (Spitzer et al. 1978) for obsessive-compulsive disorder. Particular efforts were made to exclude patients with a *primary* depressive illness (as defined by Feighner et al. 1972) from the study. Six patients were diagnosed by the RDC as suffering from a *secondary* depressive condition superimposed on the obsessive-compulsive disorder.

An eight-item subscale for obsessive-compulsive disorder (the OCD Scale, Table 1) derived from the Comprehensive Psychopathological Rating Scale (CPRS; Åsberg et al. 1978) was used to assess effects. After 5 weeks of treatment, clomipramine was significantly superior to placebo, both on the two core obsessive-compulsive symptoms (Rituals and Compulsive Thoughts) and on the entire OCD scale. Nortriptyline effects were in between clomipramine and placebo and did not differ significantly from either. The effect in the placebo-treated group was very small in spite of the supportive hospital environment. The mean score on obsessional symptoms after 6 weeks of placebo treatment was 96 percent of the pretreatment score.

After the controlled phase of the trial, all patients but two were given clomipramine *openly* in a flexible dosage (maximum 225 mg/day). During this phase, behavior therapy, according to the principles laid down by Marks (1973), was also given. On the combined treatment, 12 out of 22 patients could be classified as responders. Clinical and demographic data (including the presence or absence of secondary depression) did not predict response to the combination of clomipramine and behavior therapy.

Table 1

Items of the CPRS-Derived Rating Scales for Obsessive-Compulsive Disorder and Depression

OCD Scale	Depression Scale
1. Rituals	1. Apparent sadness
2. Inner tension	2. Reported sadness
3. Compulsive thoughts	3. Inner tension
4. Concentration difficulties	4. Reduced sleep
5. Worrying over trifles	5. Reduced appetite
6. Reported sadness	6. Concentration difficulties
7. Lassitude	7. Lassitude
8. Indecision	8. Inability to feel
	9. Pessimistic thoughts
	10. Suicidal thoughts

Both scales consist of items drawn from a larger rating instrument, the CPRS (Åsberg et al. 1978). The construction of the two subscales is similar and partially based on the incidence of symptoms in the respective disorders. Note the overlap—half of the items in the OCD scale occur in the depression scale as well.

Marks et al. (1980) compared clomipramine and placebo, with and without exposure treatment. Relaxation procedures were used to control for the time spent with the therapist. The 40 patients studied were all chronic cases with a mean duration of illness similar to those studied by Thorén et al. (1980a). Depressive symptoms were not an exclusion criterion, and pretreatment scores on a depression inventory suggested that only 2 of the 40 patients were not depressed.

The patients were given placebo or clomipramine (flexible dosage up to 225 mg/day given as a single dose at night) on an outpatient basis for 4 weeks. On subsequent admission to hospital, drug treatment was continued without further changes of dosage, and the patients were given either exposure or relaxation sessions. After 6 weeks of psychological treatment, the patients were released from hospital to continue on the drug (or placebo) treatment for another 26 weeks. Final followup was after 2 years.

A series of ratings was used to assess rituals, mood, and general adjustment. Compared to placebo, clomipramine produced significantly more improvement of all these aspects. Severity of the mood symptoms in this patient group predicted response to clomipramine. In the least dysphoric patients only the time spent on target rituals showed a significant advantage of the active drug over placebo. Exposure was connected with an amelioration of rituals. The best effect was obtained in patients who had both drug and exposure, and the effects of the two treatments appeared to be additive. Compliance with the psychological treatments was better in the patients who had received an active drug.

Montgomery (1980) studied 14 patients with severe and chronic obsessive-compulsive disorder, diagnosed by the RDC of Spitzer et al. (1978). In this study, primary and secondary depressive illness were both exclusion criteria. A crossover design was used, where each patient received either placebo or 75 mg clomipramine (given as a single dose by night) for 4 weeks, and was then crossed over to the other treatment for another 4-week period. Behavior therapy was given once weekly to all patients during the entire trial.

A six-item CPRS subscale for obsessive-compulsive disorder, and a CPRS-derived scale for depression (Montgomery & Åsberg 1979) were used to assess effects. Clomipramine was significantly better than placebo for compulsive thoughts, but not for rituals. There was no significant change in scores on the depression scale with any of the treatments.

Effects on the Serotonin System

Clomipramine is not a "pure" serotonin uptake inhibitor. It is metabolized in the body, and the main metabolite demethylclomipramine is a potent inhibitor of noradrenaline uptake (Träskman et al. 1979). The plasma concentrations of the metabolite are almost always higher than those of the parent compound after oral administration.

Clomipramine's lack of selectivity suggests that the pattern of neuronal effects may be complicated. It is, however, possible to some extent to disentangle the effects of the parent compound from those of the metabolite.

When a monoamine uptake inhibitor is given to a patient, the turnover of the respective amine is changed. This is reflected in a decreased concentration of its metabolite in the spinal fluid. Nortriptyline, for instance, is a preferential inhibitor of noradrenaline uptake and causes a reduction of the noradrenaline metabolite 4-hydroxy-3-methoxyphenylglycol (HMPG) in the spinal fluid (Bertilsson et al. 1974). Zimelidine, which is a relatively selective serotonin uptake inhibitor, causes a decrease in the spinal fluid level of the serotonin metabolite, 5-hydroxyindoleacetic acid (5-HIAA) (Bertilsson et al. 1980).

During clomipramine treatment of depression, both 5-HIAA and HMPG concentrations are reduced. The extent of the HMPG reduction is correlated to the plasma concentration of the demethyl metabolite, and the 5-HIAA reduction is a function of the plasma concentration of the parent compound. The latter association is not linear but U-shaped (Figure 1). Both very low and very high concentrations of clomipramine are associated with a smaller reduction in 5-HIAA than intermediate concentrations (Träskman et al. 1979; Thorén et al. 1980b).

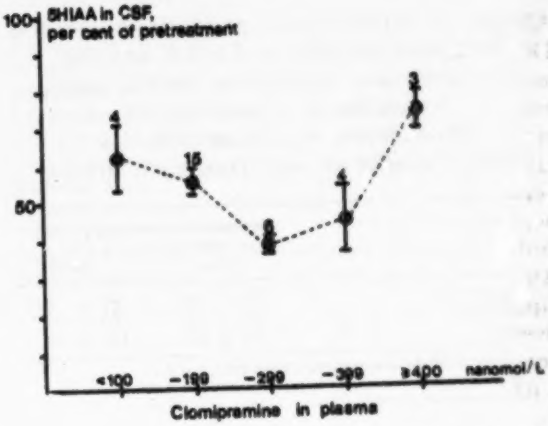

FIGURE 1. Concentrations of 5-HIAA in CSF during treatment with clomipramine (as percent of the pretreatment concentration) in relation to plasma level of clomipramine. Means, standard deviations, and number of patients are given. Both depressed $N = 24$) and obsessive-compulsive ($N = 8$) patients are included.

Thorén and co-workers (1980b) measured spinal fluid concentration of monoamine metabolites before and during treatment with clomipramine, nortriptyline, and placebo in their obsessive-compulsive patients. As expected, nortriptyline caused a reduction in HMPG, clomipramine reduced both HMPG and 5-HIAA, and placebo treatment did not change the metabolite concentrations (Table 2).

The change in 5-HIAA, but not that in HMPG, appeared to be important for the treatment outcome. There was a significant correlation between reduction in 5-HIAA and effect on the two core obsessive symptoms, rituals and compulsive thoughts—the more pronounced the reduction of 5-HIAA, the better was the effect.

This was in contrast to the effect on the remaining, "dysphoric" symptoms of the OCD scale (see Table 1), which *increased* with decreasing HMPG levels, although not significantly (Table 3). This is also in striking contrast to the pattern described in endogenous depression, where amelioration during clomipramine treatment has been found to be correlated to HMPG reduction, but not to change in 5-HIAA (Träskman et al. 1979).

Table 2

Changes in Spinal Fluid Concentrations of the Serotonin Metabolite, 5-HIAA, and the Noradrenaline Metabolite, HMPG, after Three Weeks' Treatment for Obsessive-Compulsive Disorder (Eight Patients in Each Treatment Group)

Treatment	Metabolite concentration, percent of pretreatment (mean ± SD) 5-HIAA	HMPG
Clomipramine	61 ± 14*	68 ± 6**
Nortriptyline	95 ± 16	68 ± 10*
Placebo	91 ± 27	102 ± 8

*Significant reduction compared to pretreatment, $p < 0.01$.
**Significant reduction compared to pretreatment, $p < 0.001$.
Data from Thorén et al. (1980)

Thorén et al. (1979) also correlated the treatment effect with the plasma concentrations of clomipramine and its metabolite and found a significant negative relationship between the parent compound and the effect (once more for the core symptoms only). This may seem surprising. If the best effect is obtained with a maximal reduction of 5-HIAA, and if the relationship between clomipramine concentration and 5-HIAA reduction is curvilinear, the relationship between clomipramine and effect should also be curvilinear. Closer examination of the range of levels found in the obsessive-compulsive patients explains the apparent contradiction, since almost all patients had plasma levels in the high range (and thus lie on the right limb of the U-shaped curve in Figure 1).

A curvilinear relationship between clomipramine in plasma and the effect on rituals was indeed found by Stern, Marks, Mawson, and Luscombe in their analysis of 20 of the patients studied by Marks et al. (1980). These authors also found a relationship between demethylclomipramine and one effect—the reduction of scores on the Hamilton Depression Scale. This suggests that clomipramine may account for the anti-obsessive effect and the metabolite for the antidepressant effect. (It may be recalled that depression was not an exclusion criterion in this study.)

Taken together, these findings seem to support the hypothesis of a relationship between amelioration of core obsessive symptoms (in particular, rituals) and a drug effect on serotonin neurons. The number of patients studied is, however, still too small to permit definitive conclusions. The obvious test of the hypothesis would be to try a selective serotonin uptake inhibitor, for instance, zimelidine, in a controlled trial.

Depression, Dysphoria, and Treatment Outcome

The study of Marks et al. (1980) suggests that clomipramine treatment may above all be effective in patients who have affective symptoms in addition to their rituals, while those who are not dysphoric react better to exposure. The study by Thorén et al. (1980a) can hardly be used to investigate the importance of pretreatment depressive symptoms for the effect of clomipramine, since those among the eight clomipramine-treated patients who had high scores on the depression scale also had plasma levels of clomipramine outside the "therapeutic range." The study by Montgomery (1980) cannot be used for this purpose, either, since the patients were given both clomipramine and behavior therapy.

The predictive value of pretreatment depression for the effect of the *combination* of clomipramine and behavior therapy can, however, be evaluated from the two latter studies. Montgomery (1980) explicitly excluded patients with a diagnosis of depression and was nonetheless able to demonstrate an effect, but only on obsessive thoughts. Thorén et al. (1980a) included some patients with a secondary depression, and this diagnosis did not predict outcome. The pretreatment depression scores were 14.2 ± 7.9 in the responders, and 13.0 ± 7.9 in the nonresponders to the combined treatment, a nonsignificant difference.

Patients who do not receive a *diagnosis* of depression may still have many symptoms, e.g., depressed mood, that are characteristic of depressive illness but are common in other psychiatric afflictions as well. In order to explore further the importance of pretreatment symptomatology, a factor analysis of the 14 item-scores (Varimax rotation, SPSS) was performed on the combined OCD and depression scales from the patients studied by Thorén et al. (1980). In particular, the authors were interested to see whether "depressive" or dysphoric symptoms are highly loaded in the same factor. This appears not to be the case, since classical "depressive" symptoms load on all four factors found in the analysis (Table 3). The first factor, which accounts for about half of the variance, might be labeled an "obsessive" factor, since it is the only one where rituals load strongly. It is also characterized by pessimistic thoughts, reduced sleep, worry, and a *negative* correlation with compulsive thoughts. The second factor might be described as an "anxiety" factor with high loadings for inner tension, concentration difficulties, inability to feel, and reduced appetite, but also for apparent sadness. The third factor appears to be the most "pure" depression factor with strong loadings for reported sadness, inner tension, suicidal thoughts, and reduced sleep. The fourth factor, finally, could possibly be described as an "asthenia" factor with strong loadings for indecision, lassitude, worry, and compulsive thoughts. Scores on the four factors in patients with and without a diagnosis of secondary depression are shown in Figure 2.

Table 3

Factor Analysis of Scores Given to 24 Untreated Patients with Obsessive-Compulsive Disorder on Items from the CPRS Obsessive-Compulsive Disorder and Depression Scales. Varimax Rotated Factor Matrix

Symptom	Factor 1 (49.8)	Factor 2 (20.7)	Factor 3 (15.7)	Factor 4 (13.7)
Reported sadness	25	24	94	−02
Inner tension	−01	49	55	21
Inability to feel	−12	75	11	11
Pessimistic thoughts	67	21	13	07
Suicidal thoughts	13	−11	49	20
Worrying over trifles	45	26	05	35
Compulsive thoughts	−43	14	26	36
Rituals	59	−03	07	−01
Indecision	10	−16	05	79
Lassitude	02	29	16	61
Concentration difficulties	23	48	−14	−06
Reduced appetite	30	60	24	03
Reduced sleep	62	10	39	03
Apparent sadness	43	36	18	23

The figures within parenthesis are the percentages of variance accounted for by the respective factors.

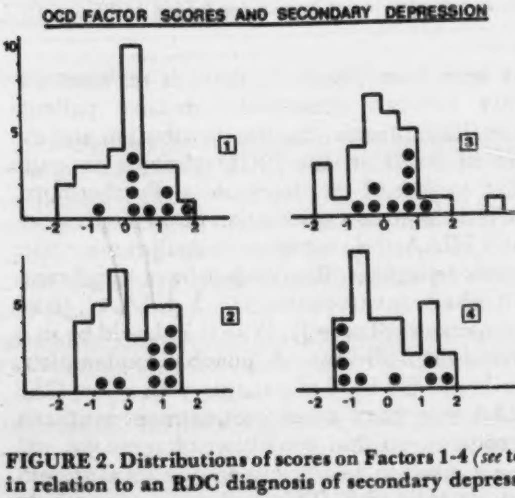

FIGURE 2. Distributions of scores on Factors 1-4 (*see* text) in relation to an RDC diagnosis of secondary depression (filled dots).

Individual factor scores were then related to outcome of the combined treatment with clomipramine and behavior therapy (Table 4, Figure 3). The two "affective" factors, the "anxiety" (2) and "depression" (3) factors correlated positively with outcome, significantly so for Factor 3. The predictive value of the factor scores was low, however and, as seen from Figure 3, some patients with very low scores on the "depression" factor reacted well to the treatment. The outcome of the factor analysis should be regarded with great caution due to the small number of patients ($N = 24$), but would seem to support the contention of Marks and coworkers (1980 and this issue) of a better treatment effect in obsessive-compulsive patients who are also dysphoric.

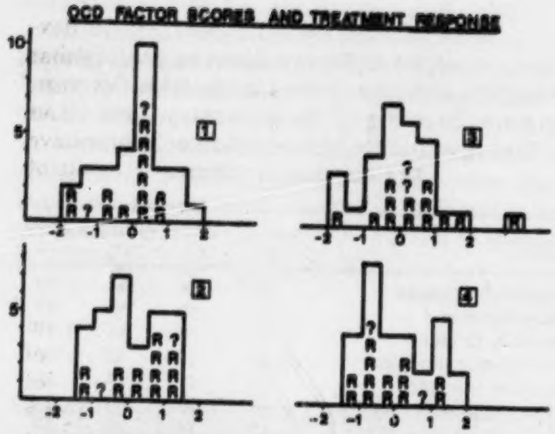

FIGURE 3. Distributions of scores on Factors 1-4 (*see* text) and response category on combined treatment with clomipramine and exposure. R denotes positive response, "?" patients who were included in the pretreatment rating but not given clomipramine plus exposure.

Table 4

Correlations Between Factor Scores and Response to Combined Treatment with Clomipramine and Exposure in 22 Patients with Obsessive-Compulsive Disorder

Factor	Pearson *r*	*p*

Biochemical Disturbances in Depression and Obsessive-Compulsive Disorders

During recent years, research in depression has largely focused on the importance of monoamine neurons and of neuroendocrine functions. Depression, particularly of the endogenous type (melancholia), has been associated with low cerebrospinal fluid (CSF) concentrations of the serotonin metabolite 5-HIAA (*see*, e.g., the review by van Praag 1981; also Åsberg et al. 1982). The low 5-HIAA levels may be characteristic only of a subgroup of patients with melancholia, since the distribution of the metabolite has repeatedly been reported to be nonnormal or bimodal (Åsberg et al. 1976). Melancholia has also been associated with a high frequency of inability to suppress cortisol secretion after administration of dexamethasone (Carroll et al. 1981). In order to elucidate the relationship between melancholia and obsessive-compulsive disorder, it might therefore be of interest to compare distributions of CSF 5-HIAA, and dexamethasone suppression, in obsessive-compulsive disorder and depression.

Figure 4 shows CSF 5-HIAA in patients with melancholia and obsessive-compulsive disorder, and in healthy controls. Only women are shown, since 5-HIAA concentrations differ between sexes, and the group of men with obsessive-compulsive disorder is too small to allow any meaningful comparisons.

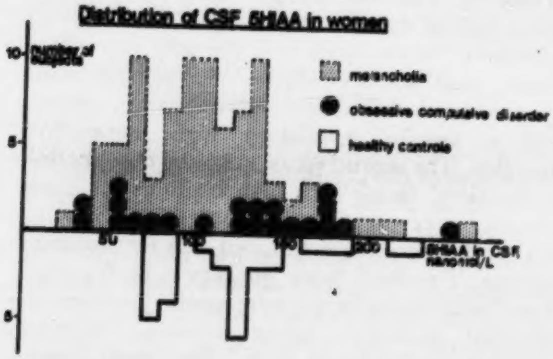

FIGURE 4. Distributions of 5-HIAA in CSF in women with melancholia and obsessive-compulsive disorder, and healthy female controls. Response to clomipramine plus exposure treatment is indicated by R. "?" indicates that response category is not known (*see* legend to Figure 3).

As seen from Figure 4, there is no *mean* difference between obsessive-compulsive patients and healthy controls, but the distribution and the range of levels in the OCD patients is quite similar to that of the depressives. Furthermore, there is a significant association between pretreatment 5-HIAA and response to clomipramine plus behavior treatment. Responders have significantly higher pretreatment 5-HIAA than nonresponders (Table 5). Why this should be so is by no means obvious. A possible explanation, however, might be that patients with a low CSF 5-HIAA may have a low pretreatment synthesis of serotonin, so that inhibition of reuptake still does not result in a sufficient amount of serotonin in the synaptic cleft. This explanation is entirely speculative but it is testable in principle since, if it were true, addition of tryptophan should lead to an increased therapeutic effect.

Table 5

Pretreatment CSF Amine Metabolite Levels in Responders and Nonresponders to Clomipramine Plus Behavior Treatment

Metabolite	Metabolite Concentration, mean ± SD (nanomol/L CSF)	
	Responders	Nonresponders
5-HIAA	137 ± 39	93 ± 49
HVA	339 ± 100	248 ± 91
HMPG	61 ± 23	52 ± 14

Data from Thorén et al. (1980).

Table 6

Dexamethasone Suppression Tests (DST) in 17 Patients with Obsessive-Compulsive Disorder

	Abnormal *N* = 7 (41%)	Normal *N* = 10 (59%)
Age (mean, SD)	44.0 (12.08)	44.90 (8.69)
Sex (women:men)	6:1	8:2
Depression score (mean, SD)	3.43 (3.40)	3.25 (1.34)
OCD scale score (mean, SD)	7.43 (3.88)	7.85 (2.61)
Obsessive symptoms score (mean, SD)	3.14 (1.65)	3.60 (0.88)
Current medication (clomipramine or drug free)	1:6	2:8
Response to clomipramine (responder ornonresponder)	5:1	7:3

None of the differences between patients with normal and abnormal DSTs are statistically significant.

Dexamethasone suppression tests (DSTs) have been performed in 17 patients with obsessive-compulsive disorder according to the RDC criteria. The tests were performed as recommended by Carroll (Carroll et al. 1981), i.e., 1 mg dexamethasone was given at 2300 hours on Day 1 and blood was drawn for analysis of cortisol (by radioimmunoassay) on Day 2 at 0800, 1600, and 2300 hours. The test was regarded as abnormal if any of these cortisol values exceeded 138 nanomol/L. In seven cases the DST was clearly abnormal. None of the background factors listed in Table 6 differed between patients with a normal or an abnormal DST, not even scores on the depression scale. This outcome would seem to cast some doubt on the specificity of the dexamethasone test for melancholia, at least as that disorder is usually defined. It does suggest, however, that some cases of melancholia and some cases of obsessive-compulsive disorder have a biochemical disturbance in common, in spite of the apparent differences in the clinical picture.

Conclusion

There is now good evidence that clomipramine is indeed an effective drug in the treatment of obsessive-compulsive illness. The presence of dysphoria in the patient may be associated with a better chance of recovery on drug treatment, but its absence does not preclude a good effect. There is indirect evidence that the serotonin effects of the drug are important for its effect on rituals, while the noradrenaline effects may be more important for depression. It may be relevant in the context that a low turnover of serotonin, as reflected in low levels of 5-HIAA in the CSF, has been associated with increased anxiety and increased aggression (Banki 1977; Brown et al. 1979, 1981; Rydin et al. 1982)—two factors that psychoanalytic theory have associated with obsessive-compulsive neurosis.

There is no evidence that the effect of clomipramine declines with time. The long-term outcome of the patients studied by our group has generally been favorable in those patients initially classified as responders (Table 7). Most of these patients are still taking the drug, but two have been drug-free for more than a year without a relapse.

Table 7

Long-Term Outcome of Clomipramine Treatment

	Responders	Nonresponders
Lost to followup	1	2
Recovered or better on clomipramine	9*	
Recovered or better, drug free	2†	
Unchanged		3
Psychosurgery		3
Schizophrenic development		1
Depression (periodic)		1

*Episodic treatment in two cases.
†Both made previous attempts to stop taking the drug, but failed. Both were drug free for more than a year.
Data from Thorén et al. (1980). The followup period varies from 5 to 7 years.

There now seems to be enough data on the effect of clomipramine in obsessive-compulsive disorder to allow the formulation of tentative guidelines for its clinical use. In patients with long-standing, severe obsessive-compulsive illness who also are dysphoric, clomipramine appears to be the drug of choice. It can be tried also in patients who are not dysphoric, but the effect is not equally convincing. The treatment effect is not fully apparent until after 5-10 weeks' treatment. Dosage should be individualized. Plasma level determinations may be of help to avoid too high or too low levels, both which seem to be connected with a poorer effect. Combination with exposure treatment is desirable. Treatment should be prolonged, probably over several years. With the exception of dental problems from the reduced production of saliva (which can be avoided by a careful mouth hygiene), no serious long-time side-effects have been described. It is important to assist the patients in recreating meaningful social relationships and activities. A common remark from patients whose symptoms diminish with drug treatment is that they do not quite know what to do with the time that they used to spend on their rituals. A few of our patients have indeed stopped taking the drug, stating that they actually preferred their rituals to an attempt to cope with the demands of an ordinary existence. But for the majority of the responders, the advantages have far outweighed these problems.

Acknowledgment: The assistance of Lisbeth Eriksson in the preparation of this manuscript is greatly appreciated.

Quo Vadis—Biology of Schizophrenia

Chair: **Edward Domino, M.D.**

Ann Arbor, Michigan

Introductory Comments

Edward F. Domino, M.D.[1]

The pathogenesis of each of the schizophrenias is very poorly understood. It is becoming apparent that no single biological theory is adequate to explain the etiology of these diseases. The evidence that current antipsychotic drugs act primarily through blockade of dopamine receptors is most convincing. However, a significant proportion of schizophrenic patients are nonresponders to antipsychotic drugs, a fact well known since their introduction in the 1950s. Even in patients who are drug responders, it seems unlikely that their psychotic symptoms are caused by excessive levels of dopamine or its turnover in the central nervous system. In fact, the clinical biochemical evidence is to the contrary. There is evidence for both supersensitivity as well as subsensitivity of dopamine receptors in some schizophrenic patients. The fact that some dopamine agonists, like apomorphine, in low doses may also temporarily relieve some symptoms of schizophrenia suggests that the discovery of new selective presynaptic dopamine receptor agonists may be a useful therapeutic approach. There is considerable evidence for multiple dopamine receptors in the brain. Our present drugs tend to act on these multiple receptors both pre- and postsynaptically. This tends to blur our thinking regarding their mechanism of action. Obviously, there is a need to discover more specific dopamine agonists and antagonists that act selectively pre- or postsynaptically on each subtype of adenylate cyclase linked and nonlinked dopamine receptors. The delayed time course of therapeutic benefit of the antipsychotic drugs suggests that more complex biochemical changes are occurring that involve other neurotransmitter systems as well. It is well known that the increase in prolactin secretion (as an index of dopamine blockade) occurs far more rapidly than the delayed antipsychotic effects of dopamine antagonists. Other putative neurotransmitters and neuromodulators including the prostaglandins, γ-aminobutyric acid, histamine, acetylcholine, phenethylamines, indolealkylamines, opioid peptides, etc. have all been implicated in schizophrenia. The structural changes in schizophrenic brains, as measured via computerized axial tomography (CAT) scans, as well as the decrease in cerebral cortical glucose utilization, as measured via positron emission tomography (PET) scans, suggests a most complex biology of schizophrenia. Where do we go from here? That is the purpose of the present workshop in which various points of view were discussed by a distinguished panel of speakers who have made important contributions to our knowledge in this field. The workshop was specifically designed to be speculative and provocative, for hopefully it will lead to new directions of research.

Two Dimensions of Pathology in Schizophrenia: Dopaminergic and Non-Dopaminergic

Timothy J. Crow, Ph.D., D.P.M., F.R.C.P., F.R.C. Psych.[1]

The belief that the primary disturbance in schizophrenia is chemical has long been plausible; that it is a disturbance of neurohumoural function is supported by observations that schizophrenic symptoms can be exacerbated in patients and provoked in nonpsychotic individuals by drugs that act on specific transmitters. The psychosis seen in some amphetamine abusers may be indistinguishable from acute paranoid schizophrenia (Connell 1958; Ellinwood 1967). The psychotic changes, like those in schizophrenia, occur in clear consciousness (that is, in the absence of disorientation) and can include first-rank symptoms (certain types of auditory hallucinations, delusions of passivity and interference, thought alienation, and delusional perception). In animals, many of the behavioral effects of the amphetamines have been shown to be due to increased dopamine release from the central dopamine pathways (Randrup & Munkvad 1967), and the psychotic changes in man seem likely also to be associated with increased dopaminergic transmission.

Mechanism of Antipsychotic Effects

Both schizophrenic symptoms and those of the amphetamine psychosis are reduced by neuroleptic drugs. Carlsson and Lindqvist (1963) found that these drugs increase dopamine turnover and suggested this was secondary to blockade of the dopamine receptor. Dopamine-induced activation of adenylate cyclase in the corpus striatum is inhibited by neuroleptic drugs; this inhibition correlates well with antipsychotic potency (Miller et al. 1974) for a range of drugs, though the butyrophenone compounds are somewhat less active than would be predicted from their clinical effects. Nevertheless, while blockade of the dopamine receptor is an obvious explanation of the extrapyramidal actions of neuroleptic drugs, some controversy exists about the extension of that mechanism to explain their antipsychotic effect. The principal argument to the contrary (Crow & Gillbe 1974) is that the correlation between extrapyramidal and therapeutic effects is not perfect. Some drugs (such as thioridazine) have fewer Parkinsonian effects than would be expected from their clinical efficacy. These same drugs, however, have high anticholinergic potency (Miller & Hiley 1974)—in other words, they have "inbuilt" anti-parkinsonian activity. When this is taken into account, the relation between dopamine antagonism and therapeutic effectiveness becomes more compelling. In the corpus striatum, where there is an interaction between acetylcholine and dopamine, drugs with a low incidence of side effects have relatively weak effects on dopaminergic transmission. This interaction may not occur in the mesolimbic dopamine system (the nucleus accumbens and related structures), and here dopamine blockade correlates better with therapeutic effectiveness (Anden 1972; Crow et al. 1977). Moreover, when dopamine antagonism is assessed not in the adenylate cyclase

---

[1] Division of Psychiatry, Clinical Research Centre, Harrow, England HA1 3UJ.

system but as inhibition of butyrophenone binding (as assay that probably identifies a second type of dopamine receptor) the relative lack of potency of the butyrophenones disappears (Creese et al. 1976; Seeman et al. 1976). A recent clinical study (Johnstone et al. 1978a) showed that only the cis- or α-isomer of the thiaxanthene flupenthixol, which blocks the dopamine receptor, is effective in treatment; the β-isomer, which is very much less potent as a dopamine antagonist, is no more active than placebo. This result is hard to explain except on the basis that dopamine antagonism is necessary for the therapeutic effects. The dopamine blockade theory of neuroleptic action has thus survived stringent tests; and antagonism of dopamine receptors, particularly those located within the mesolimbic system and the subset that is specifically labeled by butyrophenones, is most probably the critical element in diminishing schizophrenic symptoms.

Amine Theories

Is there, therefore, a primary disturbance of dopaminergic transmission in schizophrenia? Probenecid blocks the elimination of the dopamine metabolite homovanillic acid (HVA) from cerebrospinal fluid and can be used to obtain an estimate of dopamine turnover in the central nervous system. Use of this technique (Bowers 1974; Post et al. 1975) has produced no evidence of an increase in HVA that could be attributed to overactivity of dopamine neurons. Indeed, within the group of schizophrenic patients poor prognosis (Bowers 1974) and increasing severity of symptoms (Post et al. 1975) are associated with decreased concentrations of HVA in the cerebrospinal fluid. Postmortem studies (Owen et al. 1978) have also shown no evidence of increased dopamine turnover—a surprising finding, since many patients coming to necropsy have been on long-term medication. Presumably, as in animal experiments, the acute effects of neuroleptic drugs on dopamine turnover disappear with continued administration. These studies give no support to the view that dopamine neurons are overactive in schizophrenia.

By contrast, there is evidence (Owen et al. 1978; Lee et al. 1978) that the number of dopamine receptors is increased in the brains of a proportion (perhaps two-thirds) of patients with schizophrenia, as shown by receptor assay techniques. In experiments on animals, the number of receptors has been found to increase after administration of neuroleptics; but the size of the change (around 100%) in schizophrenic patients is relatively large, and there is an increase in some patients who had been free of medication for the year before death (Owen et al. 1978). Moreover, two types of dopamine receptor can be identified by ligand-binding techniques, and only that type of receptor labeled by the butyrophenone antagonist drugs is increased in schizophrenia (Owen et al. 1980; Cross et al. 1981), while receptors labeled by both antagonist and agonist compounds are increased after administration of neuroleptics (Muller & Seeman 1977).

Other neurohumoral theories have been tested in postmortem studies of the brains of schizophrenics. On the basis of the LSD psychosis and the pharmacological antagonism by LSD of some effects of serotonin, Gaddum (1954) suggested that serotonergic transmission might be deficient. Tryptophan metabolism (by way of the serotonin and other pathways), however, is not abnormal in the schizophrenic brain (Joseph et al. 1979), and serotonin receptors (assessed by binding of LSD and 5-hydroxytryptamine) are unchanged (Owen et al. 1980; Whitaker et al. 1981). There have been conflicting reports on possible changes in monoamine oxidase activity in platelets (Murphy & Wyatt, 1972) in schizophrenia, but interest in the question has been diminished by the finding (Crow et al. 1979a; 1981) that enzyme activity, assessed with several different substrates, is normal in the brains of schizophrenics. Finally, there is evidence (Crow et al. 1972) that certain noradrenergic pathways (such as the locus coeruleus innervation of the cerebral cortex) play a part in reward mechanisms; Stein and Wise (1971) suggested that these pathways degenerate in schizophrenia. A deficient response to rewarding stimuli is a plausible explanation for some features of the disease, but studies (Cross et al. 1978) of the enzyme dopamine-β-hydroxylase (a marker for noradrenergic neurons) have not shown a consistent reduction in the schizophrenic brain.

At present, therefore, the only change found consistently in the postmortem studies of the schizophrenic brain is an increase in the numbers

Table 1

Neurohumoural Hypotheses of Schizophrenia

Authors	Theory	Principal Arguments	Evidence from Postmortem Studies	
			For	Against
Gaddum 1954; Woolley and Shaw 1954	Serotonin deficiency	LSD psychosis resembles schizophrenia, LSD blocks serotonin receptors		Serotonin turnover not decreased (Joseph et al. 1979) Serotonin receptors unchanged (Owen et al. 1980; Whitaker et al. 1981)
Randrup and Munkvad 1965, 1967, 1972	Dopamine neurone overactivity	Amphetamine psychosis resembles acute paranoid schizophrenia. Amphetamines increase dopamine release. Antipsychotic drugs block dopamine receptors		Dopamine turnover not increased (Owen et al. 1978)
Bowers 1974; Crow et al. 1976	Dopamine receptor supersensitivity	As above	Dopamine receptors increased (Owen et al. 1978; Lee et al. 1978)	
Stein and Wise 1971	Noradrenaline neuron degeneration	Reward processes are mediated by central noradrenergic systems; anhedonia is a core feature of chronic schizophrenia		Dopamine-β-hydroxylase not reduced (Cross et al. 1978)
Murphy and Wyatt 1972	Monoamine oxidase deficiency	Platelet monoamine oxidase activity is reduced in some schizophrenic patients		Monoamine oxidase activity not reduced (Crow et al. 1979a)

of dopamine receptors. If this change is related to the disease process rather than to its treatment, it could explain the beneficial effects of dopamine receptor blockade.

Problems for the Dopamine Hypothesis

However, there are problems for this modification of the dopamine hypothesis.

1. It has long been recognized (e.g., Hughes & Little 1967; Letemendia & Harris 1967) that neuroleptic drugs are of limited value in many chronic patients. Moreover, Kornetsky (1976) found that such patients are sometimes resistant to the psychosis-exacerbating effects of dexamphetamine which are attributed to increased dopamine release.

2. The therapeutic effects of blockade of dopamine receptors, and possibly of neuroleptic drugs in general, are limited to "positive" symptoms (delusions, hallucinations, and thought disorder). Negative symptoms (flattening of affect, poverty of speech, loss of drive) which are more commonly seen in chronic schizophrenia, are much less affected (Johnstone et al. 1978a).

3. The fundamental defect in some chronic schizophrenic illnesses may be quite distinct from that underlying the acute disturbance. Thus, cognitive changes (e.g., disorientation in time) that resemble those seen in the organic states are seen in some institutionalized patients (Crow & Mitchell 1975; Crow & Stevens 1978). Further, several radiological studies (Haug 1962; Asano 1967; Johnstone et al. 1976, 1978b; Weinberger et al. 1979) have suggested that there is a group of chronic patients, probably including those with the greatest deterioration, who have structural changes, as reflected by increased ventricular size of the brain.

Table 2

Structural Changes in Schizophrenia—Association with Clinical State

Study	Test	N	Abnormality	Association
Holden et al. 1973	echo-ECG.	65	3rd vent.	Treatment resistance
Johnstone et al. 1976	CT scan	18	lat. vent.	Intellectual impairment (Withers & Hinton) ? negative symptoms
Rieder et al. 1979	CT scan	17	lat. vent.	Intellectual impairment (Halstead-Reitan)
Donnelly et al. 1980	CT scan	15	lat. vent.	Intellectual impairment (Halstead-Reitan)
Golden et al. 1980	CT scan	42	lat. vent.	Intellectual impairment (Luria-Nebraska)
Weinberger et al. 1980a	CT scan	51	lat. vent.	Poor pre-morbid adjustment
Weinberger et al. 1980b	CT scan	20	lat. vent.	Treatment resistance
Gross et al. 1981	CT scan	117	3rd vent.	"Pure defect" state
Andreasen 1981	CT scan	52	lat. vent.	Negative symptoms impaired sensorium
Takahashi et al. 1981	CT scan	169	3rd vent., lat. vent., cortex	Blunted affect uncooperativeness

Abbreviations: vent = ventricle
lat = lateral

A summary of the main findings of those studies (one echo-encephalographic and nine CT scans) which have related evidence of structural change to clinical features of the disease (Table 2) reveals that such changes are associated with treatment resistance (two studies), intellectual impairment (four studies), and the presence of negative symptoms (three studies). The most commonly reported abnormality is an increase in lateral ventricular area, but it may be, as suggested by Takahashi et al. (1981) that when third ventricular widening is sought, it is found to be a more consistent change.

4. It has recently become recognized that some symptoms (e.g., Schneider's first-rank symptoms) which have often been regarded as particularly characteristic of schizophrenia are relatively ineffective predictors of long-term outcome (Brockington et al. 1978; Bland & Orn 1980). This is significant in that poor outcome was the characteristic by which Kraepelin considered that dementia praecox could be distinguished from manic-depressive psychosis.

Two Syndromes

To account for these findings, it has been proposed that two syndromes can be distinguished in those diseases currently described as schizophrenic and that each may be associated with a specific pathological process (Table 3). The first (the Type I syndrome, approximating "acute schizophrenia," and characterized by the positive symptoms—delusions, hallucinations, and thought disorder) is in some way associated with a change in dopaminergic transmission; the second process (the Type II syndrome, approximating the "defect state," and characterized by the negative symptoms—affective flattening and poverty of speech) is unrelated to dopaminergic transmission but may be associated with intellectual impairment and, perhaps, structural changes in the brain. Type I symptoms are reversible; Type II symptoms, which are more difficult to define, may indicate a component of irreversibility. The former predict a potential response to neuroleptics; the latter are more closely associated with a poor

Table 3

Two Syndromes of Schizophrenia*

	Type I Syndrome	Type II Syndrome
Symptoms	Positive symptoms (delusions, hallucinations, thought disorder)	Negative symptoms (affective flattening, poverty of speech, loss of volition)
Type of illness in which most commonly seen	Acute schizophrenia	Chronic schizophrenia
Potential for response to neuroleptics	Good	Poor
Presence of intellectual impairment	Absent	Sometimes present
Outcome	Reversible	? Irreversible
Pathological process	Disturbance of dopaminergic transmission (? increased dopamine receptors)	Cell loss leading to structural changes in the brain

*Crow, T.J. *Br. Med. J.*,280-66-68, 1970.

long-term outcome.

Even if the Type I and Type II syndromes represent different dimensions of pathology, it is apparent that they do not constitute separate diseases.

They are often associated together. For example, episodes of the Type I syndrome (positive symptoms) often progress into the Type II syndrome defect state with or without the persistence of positive symptoms; this might be described as classical Kraepelinian schizophrenia. On the other hand, either syndrome may occur alone. Thus, a pure Type I syndrome which remits may be described as a schizophreniform psychosis (Langfeldt 1960), or "psychogenic" or "reactive" schizophrenia (Faergeman 1963), a cycloid psychosis (Leonhard 1966; Perris 1974), schizo-affective psychosis (Kasanin 1933), or good-prognosis schizophrenia (Vaillant 1964).

The Type II syndrome may occur alone as in simple schizophrenia or in the defect state when positive symptoms have disappeared, and sometimes it may precede the onset of positive symptoms—as in the concept of childhood asociality propounded by Quitkin et al. (1976).

The paranoid/non-paranoid dichotomy can also be related to the concept, paranoid schizophrenia being equivalent to a chronic Type I syndrome, while non-paranoid schizophrenias (including the Bleulerian categories of hebephrenia and simple schizophrenia) are those which include a component of the Type II syndrome. A similar distinction is made by Winokur and Tsuang (1981). The relationship proposed between the two syndromes is indicated in the Figure, together with the correspondence of the three symptom constellations to various nosological terms of current or recent usage.

Of particular interest are the changes which occur with the passage of time. Thus, patients with the Type I syndrome may progress to acquire Type II symptoms, and in due course some of these will lose their positive symptoms. Some may re-acquire them, i.e., experience acute exacerbations of psychosis. What appears to be unusual, and if it does occur is worthy of note, is that patients with negative symptoms (Type II syndrome) should lose these symptoms once they are

established. According to the hypothesis, this is because such symptoms are associated with a structural change in the brain.

The distinction between Type I and Type II syndromes explains a number of findings:

1. Angrist et al. (1980a) found that exacerbation of symptoms in individual patients by amphetamine predicted good response to neuroleptics, while absence of response to amphetamine predicted poor response. Re-analysis of individual Brief Psychiatric Rating Scale (BPRS) symptom scores (Angrist et al. 1980b) revealed that positive symptoms (the Type I syndrome) were exacerbated by amphetamine and improved by neuroleptics, while negative symptoms (the Type II syndrome) showed little change with either drug.

2. In a 30-year followup study, Tsuang (1980) found that disorientation at the time of first psychotic illness is a predictor of poor long-term outcome. Thus, disorientation in the acute illness may be a harbinger of the intellectual impairment of the Type II syndrome.

3. Recently, Owens and Johnstone (1980) have found that negative symptoms in long-stay patients are strongly correlated with intellectual impairment (the Type II syndrome) and also with neurological signs, but that none of these features is significantly related to positive symptoms (the Type I syndrome).

4. The prediction that increased dopamine receptors are related to positive symptoms has been tested in a study of 14 patients whose clinical state had been assessed before death on standardized rating scales. The number of dopamine receptors assessed as maximum spiroperidol binding was found to be significantly ($p < 0.01$) associated with positive but not negative symptoms (Crow et al. 1981).

Causation

The cause of schizophrenic illness remains obscure. A genetic influence is undoubted, but the facts that the onset of symptoms is often in adult life and that concordance in monozygotic twins (about 50%) falls short of 100 percent suggest that genes may be relevant only in predisposing to some other factor. Infection with slow virus may be relevant (Crow et al. 1979b; Crow 1978, 1980, 1981; Tyrell et al. 1979; Albrecht et al. 1980). Some neurotropic viruses (i.e., polio, herpes, simplex and zoster) are selective in the cells that attack. Conceivably a slow virus infection might be associated either with a primary chemical disturbance (i.e., through an affinity for a receptor site), as in the Type I syndrome, or with a more general disturbance of higher cognitive functions associated with structural changes in the brain, as in the Type II syndrome.

Schizophrenia and Late Maturational Brain Changes in Man[1]

Irwin Feinberg, M.D.[2]

Recent findings in neurobiology suggest that maturational changes take place in the brain much later in life than had previously been thought. In this context, several lines of evidence suggest that a major reorganization of the human brain takes place in adolescence:

1. There is a marked decline in the abundance of deep (Stage 4) sleep and in the amplitude of the delta waves which characterize this stage. Between the ages of 10 and 16 years, these variables show as much change as they do over the next 30 years (Feinberg & Carlson 1968; Feinberg et al. 1977; Williams et al. 1974).

2. A marked diminution in neuroanatomical plasticity occurs. For example, a left hemisphere

---

[2] Veterans Administration Medical Center and The University of California at San Francisco 94121.

lesion which causes aphasia in a 10-year-old child is usually followed by full recovery of speech if the right hemisphere is spared: the same lesion in a 20-year-old person results in a permanent aphasia.

3. The ability to carry out sustained logical thinking and to solve complex and abstract problems emerges in full flower toward the end of adolescence. While these skills surely depend upon continued learning, they may also require morphological changes in the neural substrate of thought.

4. The changes listed above are normal developmental phenomena. An abnormal developmental occurrence in adolescence is the emergence of schizophrenia. To be sure, some patients who develop this illness have a long history of behavioral disturbance so that one may question how important a role adolescence itself plays. However, one also finds patients whose psychosocial development was normal or outstanding prior to the onset of a schizophrenic illness. The abrupt change from a social, productive, and happy youngster to a delusional, withdrawn, and frightened schizophrenic is one of the most tragic events in medicine. The profound nature of this change suggests that the neural substrate of behavior has altered in some fundamental way.

Recently, Peter Huttenlocher (1979) of the University of Chicago described a late change in brain morphology which might underlie the striking behavioral and electrophysiological changes of adolescence. He observed a marked reduction in the density of synapses in postmortem specimens of human cortex between ages 2 and 16 years; most of this change seems to take place in late childhood and early adolescence. Huttenlocher's finding (as he himself suggested) could directly account for the reduction in neuroanatomical plasticity which occurs during adolescence. It could also underlie the decline in delta wave amplitude during sleep. The electroencephalogram (EEG) recorded at the scalp is the summation of slow, synchronous potential changes in large neuronal pools; a decrease in connectivity could reduce the size of the neuronal groups capable of synchronous discharge.

The author has commented on the fact that adolescence is characterized by the emergence of the ability to carry out sustained logical operations and solve complex and abstract problems. It might seem counter-intuitive to suggest that a neuronal change contributing to this cognitive development is an actual decline in neuronal connections. But this may well prove to be the case. One plausible model, consistent with Huttenlocher's data, is that shortly after birth all potentially useful interconnections develop. This extremely high density of synapses permits great plasticity but has a cost to information processing: too many neuronal connections may make it difficult to distinguish and organize functionally the particular neuronal chains required for sustained logical thought and problem solving. When, toward the end of adolescence, the connections needed for adaptation have been specified by the organism's interaction with the environment, unexploited connections are eliminated. The effect of this elimination is to reduce neuroanatomical plasticity but to increase certain information-processing capacities.

If synaptic pruning of this sort actually takes place, it would not be the first example of systematic creation and elimination of redundant neural elements in brain development. Programmed cell death (Cowan 1973) plays an important role in regulating the development of the nervous system. In the course of embryologic development, many excess neurons are regularly produced; at later and highly predictable stages, those neurons which have not achieved their appropriate connections die. This mechanism is so highly reproducible that it must be under precise genetic control; so also, one would postulate, is the elimination of redundant synapses much later in development. The mechanisms by which the synapses are eliminated is unknown, but it seems likely that neuroendocrine processes play an important role.

If a widespread, genetically programmed elimination of synapses occurs in adolescence, an error in this process may give rise to schizophrenia. The defect might result from the elimination of too many, too few, or the wrong connections. Elsewhere (Feinberg 1978), it was suggested that corollary discharge mechanisms (Evarts 1971) play an important role in the control of thinking, and that several cardinal symptoms of schizophrenia could be understood as resulting from failure of similar mechanisms in the "motor systems" of thinking.

We have already noted that the extent of neuronal interconnections might determine the size of the neuronal pools whose synchronous, slow potential change gives rise to delta waves. In this regard, it is of interest that the most firmly established brain abnormality in schizophrenia is a reduction in Stage 4 sleep (Feinberg & Hiatt 1978). This abnormality, although neither specific to, nor invariably present in, schizophrenia, has been found in 40-50 percent of the samples of schizophrenic patients investigated. Computer analysis suggests that it is largely due to reduced delta wave amplitude in the first period of non-REM sleep (Hiatt, Floyd, & Feinberg, submitted for publication).

The highly speculative nature of this discussion is obvious. But whether or not its neuroanatomic basis is the change in synaptic density described by Huttenlocher, there is compelling but as yet neglected evidence that a major reorganization of the brain takes place in adolescence. This reorganization is associated with striking changes in sleep EEG, brain plasticity, and problem-solving capacity. An error in so pervasive a developmental process may be responsible for some types of schizophrenia.

Dopamine and the Neural Substrates of Depression

Chair: Hans C. Fibiger, Ph.D.
University of British Columbia
Vancouver, B.C., Canada

Evidence in Support of a Role of Dopamine in Affective Illness

Angelos E. Halaris, M.D., Ph.D.[1]

The first indications of a link between dopamine (DA) and affective disorders appeared in the late sixties. It was not until recently, however, that serious consideration was given to DA in addition to other neurotransmitters commonly associated with the pathophysiology of manic-depressive illness. A growing body of evidence suggests that along with norepinephrine (NE) and 5-hydroxytryptamine (5-HT), DA plays a role in affective illness. Newer compounds with selective effects on DA receptors and specific DA agonist or antagonist activity are assisting in the characterization of various subtypes of depression. Correlations between forms of psychopathology and DA metabolism have clearly defined a group of depressives with diminished excretion of homovanillic acid (HVA) in cerebrospinal fluid (CSF). These studies have associated DA with retarded forms of depression and certain aspects of manic behavior.

Compared to the extensive literature on antidepressants and NE or 5-HT, animal studies seeking to establish dopaminergic involvement in antidepressant drug action are relatively sparse. There are two reasons for this disparity. First, DA was long held to be a precursor of NE, lacking any transmitter activity of its own. This assumption later proved to be erroneous. Second, research has focused heavily on NE as the transmitter primarily responsible for the pathogenesis and treatment of affective illness. Thus, the number of basic studies concerned with antidepressant action and dopaminergic transmission is small.

Effect of Tricyclics on DA Metabolism

One of the earlier findings from this laboratory was that chlorimipramine and other tertiary drugs increased DA levels in rat whole brain. The increases were substantial (40-60%) and time-dependent. Since similar time-dependent changes had been obtained with brain levels of 5-HT after chlorimipramine, it was hypothesized that there may be a link between uptake inhibition and changes in amine metabolism, possibly via feedback mechanisms or a direct effect of tricyclics on neuronal firing. This hypothesis led to the detection of DA uptake inhibition by chlorimipramine and other psychotropic compounds. These findings were later confirmed by Ghosh and Hrdina (1977), who obtained marked increases in striatal DA (up to 140%) with imipramine, desmethylimipramine, and amitriptyline. The increase was time-dependent and biphasic. There were concomitant alterations in levels of HVA which were a mirror image of the changes in the concentration of DA. The authors hypothesized that the ability of tricyclic antidepressants to affect striatal concentrations of DA and HVA are relevant to the beneficial effects of these agents in the treatment of Parkinson's disease.

Antidepressant Drugs and Dopamine Uptake

Reuptake blockade of NE and 5-HT by antidepressants and a consequent shift in amine metabolites have been key findings for inferring the therapeutic mode of action of antidepressants and, by extension, the biochemical substrate of affective illness. The possibility that tricyclic antidepressants also inhibit DA uptake had been largely ignored or considered to be of little pharmacological and clinical significance. Using synaptosomal preparations from rat whole brain, it was demonstrated that a number of antidepressants block DA uptake (Halaris et al. 1975; Halaris & Freedman 1975). The degree of inhibition was variable and could not be systematically explained on the basis of molecular structure or side-chain substituents. In the group of antidepressants, it was not possible to detect differences in potency between secondary and tertiary drugs. Among those drugs tested, some secondary (nortriptyline and protriptyline) and some tertiary (chlorimipramine and amitriptyline) tricyclics were potent agents in inhibiting DA uptake. Desipramine, imipramine, and doxepin were weaker, as were iprindole and the tetracyclic maprotiline.

The tricyclic drug concentrations required to produce 50 percent inhibition of DA uptake (IC50 values) were initially considered to be high compared with IC50 values for NE and 5-HT uptake. However, IC50 values obtained in whole rat brain preparations can be misleading, since specific brain regions may exhibit selectivity for inhibition of DA uptake. When regional analysis of DA uptake was performed, the *hypothalamus* was the region in which tricyclic (and nontricyclic) antidepressants produced *in vitro* uptake inhibition in the micromolar range (Table 1). Kinetic analysis revealed that uptake inhibition was of the competitive type. It is noteworthy that iprindole—which has no effect on NE uptake—also inhibited DA uptake in the micromolar range.

In another study, selected tricyclics were injected into rats acutely or chronically. The uptake experiments were performed with synaptosomal preparations from whole brain of pretreated animals. Chlorimipramine, among the most potent antidepressants to inhibit DA uptake, produced significant inhibition, indicating that the drug reaches active sites in spite of the fact that preparations from whole brain rather than hypothalamus were used. Similar results were obtained when lower doses were given for 3 weeks.

Finally, the specificity of the accumulation of labeled amines when performing uptake experiments has often been questioned. It has been

Table 1

Dopamine Uptake in Hypothalamus

Drug	IC_{50} (M)
Desipramine	4.2×10^{-6}
Doxepin	4.4×10^{-6}
Clomipramine	6.3×10^{-6}
Imipramine	7.3×10^{-6}
Bupropion	2.0×10^{-6}
Iprindole	2.2×10^{-6}
Pridefine	2.5×10^{-6}

suggested that biogenic amines can be taken up by nerve-endings other than those of the transmitter used. This is likely to occur at high substrate concentrations. However, if the concentration of labeled amine is less than the Km for the high affinity uptake system, then the risk of nonspecific accumulation is minimized. To rule out that tritiated DA is partially taken up by noradrenergic terminals in hypothalamus, the freely cycling female rat was used as a test model. It was demonstrated that the cyclic and phase-dependent pattern of DA uptake by hypothalamic nerve-endings differs completely from that of NE in the course of a full estrous cycle (Davis et al. 1977, 1978). If tritiated DA were entering NE terminals, the resulting pattern of DA uptake during the various phases of the rat estrous cycle would be similar, if not identical, to that of NE.

Uptake inhibition of DA is not unique to tricyclic antidepressants. A number of newer compounds exhibit significant inhibitory activity. In a comparative study of such new antidepressants, Randrup and Braestrup (1977) investigated the potency of a number of conventional and newer drugs on the inhibition of NE, DA, and 5-HT uptake. Their results indicate that the newer antidepressants butriptyline, mianserin, and trimipramine are about equipotent with maprotiline, iprindole, and the classical tricyclics in inhibiting striatal DA uptake. Interestingly, nomifensine, a clinically efficacious antidepressant (Pecknold et al. 1975) is one of the most potent inhibitors of DA uptake; it is equally potent with benztropine and seven times more potent than cocaine.

The Case of Bupropion (Wellbutrin^{R})

Bupropion is a phenylethylamine derivative with clinically established antidepressant activity. Its chemical structure differs from that of conventional antidepressants, and the compound does not significantly affect norepinephrine or serotonin. A number of clinical studies have confirmed that bupropion is significantly better than placebo. Bupropion may exert its antidepressant effects via direct or indirect stimulation of DA receptors. To assess whether bupropion is a direct or indirect DA agonist, two types of experiments were performed. First, the effect of bupropion on DA uptake in striatal synaptosomal preparations was determined. Second, use was made of the stereotypy response believed to be mediated by striatal dopaminergic neurons. The uptake experiments revealed bupropion to be a moderately potent inhibitor of striatal DA uptake (Table 2). When injected into rats, it elicited stereotyped behavior in a dose-dependent manner. Since these experiments did not differentiate between a direct vs. indirect DA agonist activity of bupropion, an animal model for surgical induction of DA receptor supersensitivity was devised. This model will be discussed briefly.

By means of parasaggital knife cuts performed bilaterally, the ascending nigrostriatal fibers were transected prior to their entry into the striatum. The lesion resulted in a 96 percent depletion of striatal DA by the fourteenth day after surgery. Bupropion produced intense stereotyped behavior in lesioned animals on Days 3 and 7 after surgery

Table 2

Effect of Bupropion (Wellbutrin^{R}) on Biogenic Amine Uptake

Amine/Region	IC_{50} (μM)
DA - Striatum	1.5
DA - Hypothalamus	2.0
NE - Hypothalamus	2.6
5-HT - Cortex	154.5

at doses that did not induce stereotypy in sham-lesioned controls. Since DA depletion in striatum was not complete 1 week post-lesion, the appearance of intense stereotypy in lesioned animals was probably due to supersensitive DA receptors responding to enhanced dopaminergic transmission caused by reuptake blockade. However, on the fourteenth day post-lesion, when DA depletion was virtually complete, the stereotypy response of the lesioned animals was much weaker. Since presynaptic terminals have undergone degeneration by 14 days after axotomy, the ability of bupropion to elicit stereotyped behavior at this time is probably due to a direct effect on DA receptors. Therefore, it appears that bupropion is a mixed direct/indirect DA receptor agonist.

Bupropion had no significant effects on 5-HT uptake. While an effect of the drug on noradrenergic transmission has not been ruled out, bupropion appears to act primarily via a dopaminergic mechanism. Whether the results from the above animal experiments can explain bupropion's clinical antidepressant efficacy remains to be established.

Behavioral Effects and Conclusions

Two reports have described behavioral effects of tricyclic antidepressants mediated by dopaminergic mechanisms. Molander and Randrup (1976a,b) used gnawing behavior in mice as an index of dopaminergic activity. The antidepressants tested potentiated gnawing induced by levodopa in combination with a decarboxylase inhibitor. In a followup study, these drugs also potentiated the apomorphine-induced gnawing. The authors concluded that tricyclics enhance behaviors associated with brain DA.

Taken together, the above observations give strong support to the contention that tricyclic and non-tricyclic antidepressants affect dopaminergic transmission in the CNS. These drugs exert significant effects on the uptake and metabolism of brain DA and potentiate behavioral effects commonly attributed to dopaminergic mechanisms. However, the relevance of the animal studies to the clinical efficacy of tricyclic antidepressants, the induction of mania in susceptible manic-depressives, and the exacerbation of schizophrenia with these drugs remains to be established. Certainly, the clinical effects of the newer, non-tricyclic antidepressants, such as nomifensine and bupropion, compel attention to DA as a neurotransmitter involved in manic-depressive illness.

Mania, Depression, and Brain Dopamine: An Overview

Axel Randrup, Ph.D.,[1] Ib Munkvad, M.D.,[1] and Rasmus Fog, M.D.[1]

Dopaminergic mechanisms in the brain seem to be importantly related to the pathogenesis and treatment of several neuropsychiatric diseases, i.e., mania, depression, schizophrenia, Parkinson's disease, and Gilles de la Tourette's disease.

The relation with the affective disorders was suggested in the early 1970s by the following: antimanic, antidepressive, and depressogenic effects of neuroleptic drugs (dopamine blockers); effects of amphetamines, apomorphine, and L-DOPA (dopamine agonists) on mood and affective diseases; correlation of Parkinsonism and other disorders of the basal ganglia with depression; effects of thymoleptics on animal behavior believed to be associated with changes in brain dopamine, etc. (Randrup et al. 1973a, 1973b, 1975). In the years following, this body of evidence was strengthened by new findings: Involvement of dopamine in an interesting monkey model of depression and in reward mechanisms; marked effects on lithium on supersensitive postsynaptic dopamine receptors and on the turnover of dopamine; effects of tricyclic thymoleptics and electrostimulation (both after repeated application) on dopamine receptors; dopaminergic effects of second generation antidepressive drugs, particularly nomifensine, bupropion, and amoxapine) Harrison-Read 1981; Randrup et al. 1979, 1981a; Serra et al. 1980, 1981; present study group).

The dopaminergic effects of chronic thymoleptics seems to be associated with mild excitatory effects on behavior, but these drugs can also be sedative and exert stress-protecting effects somewhat similar to the "neuroleptic indifference." The mechanisms of these effects are yet largely unknown, although there is evidence indicating dopaminergic involvement. But animal experiments are possible here, and this appears to be a particularly interesting area for future research (Pekkarinen, 1970; Garzon & Del Rio 1981).

Amphetamines produce abnormal behavior in animals and humans, which has been studied as a model psychosis. Stereotypy is a prominent feature of the abnormality, and this feature has a particularly strong correlation with brain dopamine. Many types of behavior can become stereotyped e.g., sniffing, biting, locomotion, aggressive-defensive posture and, in humans, also mental activities such as thinking. Stereotyped thinking can, for example, consist in rumination on one or a few paranoid ideas. Behavioral and mental stereotypies are also common in endogenous psychoses, and the present investigators have pointed out that constant or long-lasting affects (e.g., melancholic mood) might be regarded as an analogy, in the affective area, of stereotyped thinking and behavior (Randrup et al. 1981a, 1981b).

The hypothesis that brain dopamine is importantly related to mood and affective disorders has been strengthened by recent evidence, but it has also become increasingly clear that the relation is not a simple one, and more is known now about the interaction of dopaminergic and nondopaminergic systems in the brain.

A Mathematical Model for the Effect of Tetrahydrobiopterin Level on Tyrosine Hydroxylase Kinetic Fluctuations[1]

Patrick V. Russo, B.S.[2]

For twelve years Mandell's group, among others, has been studying the regulation of brain tyrosine hydroxylase and tryptophan hydroxylase and using in traditional kinetics experiments the saturating conditions prescribed by the Michaelis-Menten approach (Mandell 1978). However, during the last several years it has become clear that physiological concentrations of the substrates tyrosine and tryptophan and their cofactor tetrahydrobiopterin (BH_4) in brain are well below saturation; they are, in fact, below their K_m for their respective enzymes (Friedman et al. 1972; Wurtman et al. 1974; Bullard et al. 1978; Mandell et al. 1980; Lovenberg et al. 1982). Therefore, the group has undertaken kinetic experiments in which assay concentrations of coreactants are brought as near as possible to physiological levels, and the enzyme activities are sampled at fine-grained intervals of observation across time or across increasing reactant concentration.

Figure 1 is a schematic comparison of results obtained with saturating vs. non-saturating substrates. Observe the reiterative multiple velocity plateaus generated by the non-saturating condition for both time courses and substrate kinetics. What at first appeared to be noise was shown eventually to be small but reproducible

variance which required for its quantification a fresh analytical approach.

Time series analysis was found to be a useful descriptive tool. Time courses and substrate kinetics are detrended by linear regression with subsequent normalization to remove the slope and intercept. The raw data are thus transformed to a zero-mean time series of A values, allowing analysis of both its amplitude and frequency components.

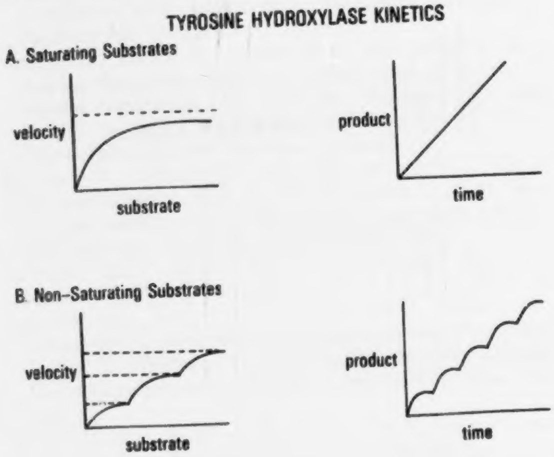

FIGURE 1

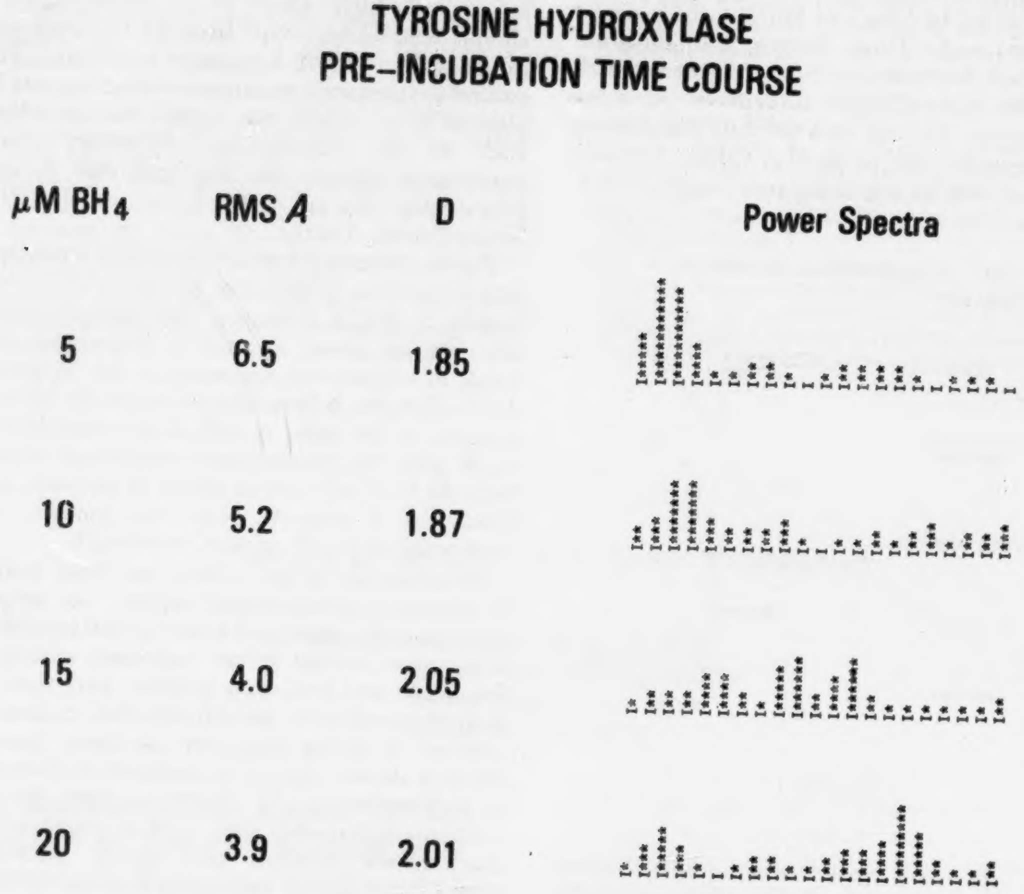
One measure of amplitude is root mean square (RMS) of A, defined as $\sqrt{\Sigma A^2/t}$. Squaring the individual values removes the negative ones, so the greater the amplitude or energy of the fluctuations, the higher the average RMS_A. To characterize its frequency or periodic nature, the series is subjected to Fourier analysis, and the resulting power spectrum reveals the relative amounts of power occurring across a range of frequencies. In addition, the Hausdorff-Besicovitch dimension D (Mandelbrot 1977) has provided an index of composite frequency or the dimensionality of the system. These qualitative metrics and their derivation appear in detail in several publications (Knapp et al. 1981, 1982; Knapp & Mandell 1982; Mandell & Russo 1981; Mandell et al. 1982).

In many systems there is a negative correlation between frequency and amplitude, for example, in the electroencephalograph (EEG) where fast waves are typically low voltage and slow waves are generally high voltage. In the present studies a similar relationship exists between D (composite frequency) and RMS (composite amplitude). For control preparations the negative slope appears in plots of D vs. RMS, but certain manipulations such as the introduction of certain pharmacological ligands can uncouple that inverse relationship (Knapp 1982; Knapp et al. 1982; Mandell et al. 1982).

Figure 2 shows the usual D vs. RMS relationship in tyrosine hydroxylase as well as the power spectra as BH_4 is increased. The asterisks represent relative power at various frequencies; the range of frequencies, expressed in the reciprocal as wavelengths, is from 80 minutes on the left to 2 minutes on the right. As BH_4 is increased from 2 to 20 μM, the predominant wavelength moves from 40 to 20 minutes to about 10 minutes, and finally to 4 minutes, with the possible reemergence of the 40-minute wavelength.

Examination of the effects on these indices of various pharmacological agents (i.e. propranolol, amphetamine) and experimental conditions shows that instead of an unlimited variety of amplitude and frequency profiles, only three or four are possible for the reproducible variance to inscribe. A strong frequency can form, become faster or slower, change in amplitude or dampen, or randomize into a chaotic regime. Several mathematical models were tried in searching for characteristic profiles, and several nonlinear dynamical systems suggested that the profiles could be simulated mathematically (Lorenz 1963; May 1976, 1980; Rössler 1976).

Mathematically, the simplest example is from an equation used in population dynamics and reviewed by May (1980). The limited range of possible profiles is shown in Figure 3. The reiterative equation contains only one parameter, the force term r, which is increased to the values shown in the respective panels with the following results. The system moves from equilibrium at $r = 1$ to a damped oscillator around $r = 2$, to a fast limit cycle around $r = 2.5$. At $r = 3.92$ a slower limit cycle is apparent; at $r = 4.0$ a chaotic regime is seen; finally at $r = 6$ the system is at equilibrium or death. The force term r is reminiscent of changing BH_4 cofactor level in the enzyme assays. At very high levels of BH_4 no fluctuations



TYROSINE HYDROXYLASE

FIGURE 2

are observed (not unlike the equilibrium "death" at a very high *r* value, Figure 3). At low or intermediate levels of BH_4 or substrate, long or short wavelengths predominate, with "chaotic" regimes interspersed.

In sum, because endogenous levels of substrate and cofactor in brain as well below saturation, valuable new information may be obtained with subsaturating, more nearly physiological assay constituents, and the subsequent application of appropriate mathematical descriptors of the dynamical character of the resulting data.

Ordering the Fluctuations of Tryptophan Hydroxylase: Lithium and Chlorimipramine[1]

Suzanne Knapp, Ph.D.[2]

Tryptophan hydroxylase (TPOH; E.C.1.14.16.4) demonstrates stable hyperbolic kinetic functions under equilibrium assay conditions, i.e., when concentrations of substrate (tryptophan) and cofactor (tetrahydrobiopterin, BH_4) are saturating. However, as the concentration ratio of cosubstrates and enzyme approaches unity the system becomes unstable, manifesting kinetic functions with reiterative plateaus across increasing cofactor concentration (Knapp & Mandell 1979). Measures of TPOH activity under non-equilibrium conditions across small increments of cofactor concentration or time have shown velocity fluctuations characterized by multiple saturation plateaus over cofactor and multiple power (frequency) spectral peaks over time, suggesting that the population dynamics of a complex system of dissipative oscillators may be reflected in the enzyme's kinetic processes (Knapp & Mandell 1982; Knapp et al. 1981).

In clinical studies, lithium slows the frequency and reduces the amplitude of the recurring mood cycles characteristic of manic-depressive disease (Schou 1973). Likewise, at the macromolecular level, lithium slows the frequency of Purkinje cell discharge rate (Schultz et al. 1981), of neurotransmitter receptor rhythms in the central nervous system (CNS) (Kafka et al. 1982), and of electroencephalograph (EEG) (Itil & Akpinar 1971), and reduces the amplitude of evoked field potentials of dentate granule cells in rat hippocampal slices (MacVicar et al. 1981). Tricyclic drugs, which share with lithium clincial antidepressant properties, also slow the frequencies of Purkinje cell discharge rates (Schultz et al. 1981) and CNS receptor rhythms (Kafka et al. 1982). This report describes the effects of lithium and the tricyclic antidepressant chlorimipramine (CMI) on the frequency and amplitude components of rat raphé TPOH velocity fluctuations

observed in both short and long residence time kinetics.

In variational kinetic studies, the fundamental unit of data is the amplitude of deviation (A) of each averaged product concentration point at a given coreactant concentration or time from the mean velocity function as determined by linear regression analysis, normalized for slope and intercept. Computer routines are available from the International Mathematics and Statistics Library with which to perform time series analysis on the A values. The average amplitude or energy of the process is calculated as the root mean square (RMS) of A. The "frequency morphology" of the enzyme population of dissipative oscillators is determined using autocorrelation functions, power spectra, and an independent descriptor, the Hausdorff-Besicovitch dimension D (Mandelbrot 1977), a scale-invariant exponent reflecting the complexity of the perimeter of the one-dimensional A map of the complex function. The rougher the surface of the A function, the more often it changes direction, the longer the perimeter, and the higher the value of D, indicating an increase in degrees of freedom, fluctuation frequency, and the dimensionality of the system. Changes in D of 0.04 to 0.06 are replicable. The analytic methods used are further

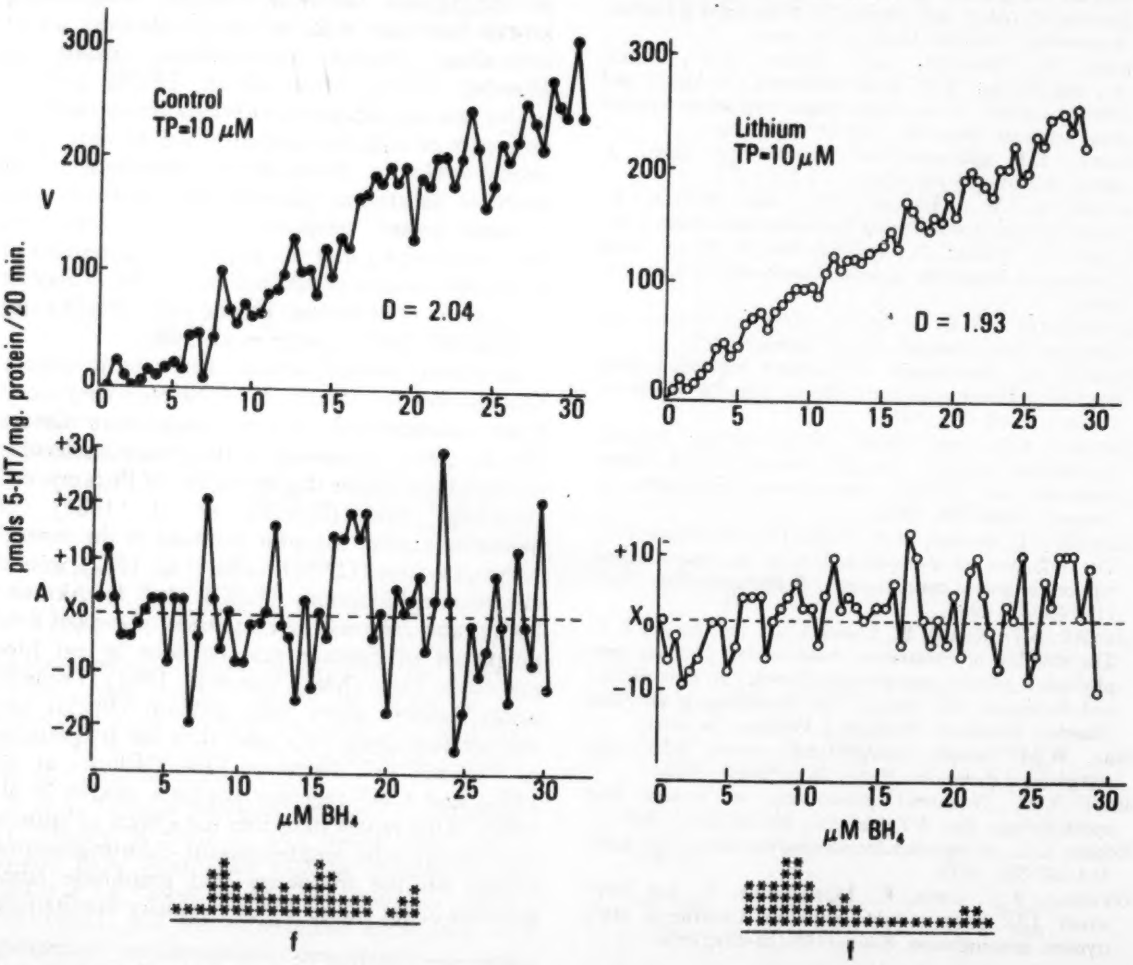

FIGURE 1. Cofactor-velocity functions, A-value transforms, and power (frequency) spectra of TPOH kinetic behavior in the absence and presence of 3 μM lithium.

detailed elsewhere (Mandell & Russo 1981).

Figure 1 presents the results from typical fluctuation experiments in which average product concentrations were determined from 60 duplicate assays across cofactor concentration at intervals of 0.5 μM BH_4. The upper portion of the figure shows the velocity functions obtained in the absence and presence of 3 μM lithium. Below them are shown the A value transforms, which clearly illustrate a lithium-induced reduction in the amplitude of variation. Fourier transformation of the A values from each experiment yielded the power spectra shown, in which the abscissa represents frequency in intervals of cofactor concentration, and the ordinate represents the distribution of power. The diffuse distribution of peaks across the control spectrum suggests multiple subpopulations of phase; in the presence of lithium a single broad peak is observed in the range of increasing cofactor concentrations, consistent with the ion reducing the heterogeneity of the enzyme population. The lower D value also reflects the slower fluctuation frequency in the presence of lithium (1.93 vs. 2.04 for the control sample).

Figure 2 demonstrates the relationship between the average frequency (D_A) and amplitude log (RMS_A) of TPOH when assayed across time in the absence and presence of lithium or CMI. Each point represents the average frequency and amplitude values from one independent experiment; each experiment consisted of 60 duplicate assays performed across time at concentrations of tryptophan and BH_4 that were held near physiological levels, 10 μM and 20 μM, respectively. On the left, the diffuse scatter of points around a negative slope is consistent with the unstable, variably coupled subpopulations postulated for the control population of enzyme oscillators in the absence of a stabilizing ligand. The negative slope reflects the inverse relationship usually observed between frequency and amplitude. The presence of lithium changes that relationship, as is indicated by the positive slope and the relatively tight distribution of points around it (correlation coefficient $r = 0.765$). CMI

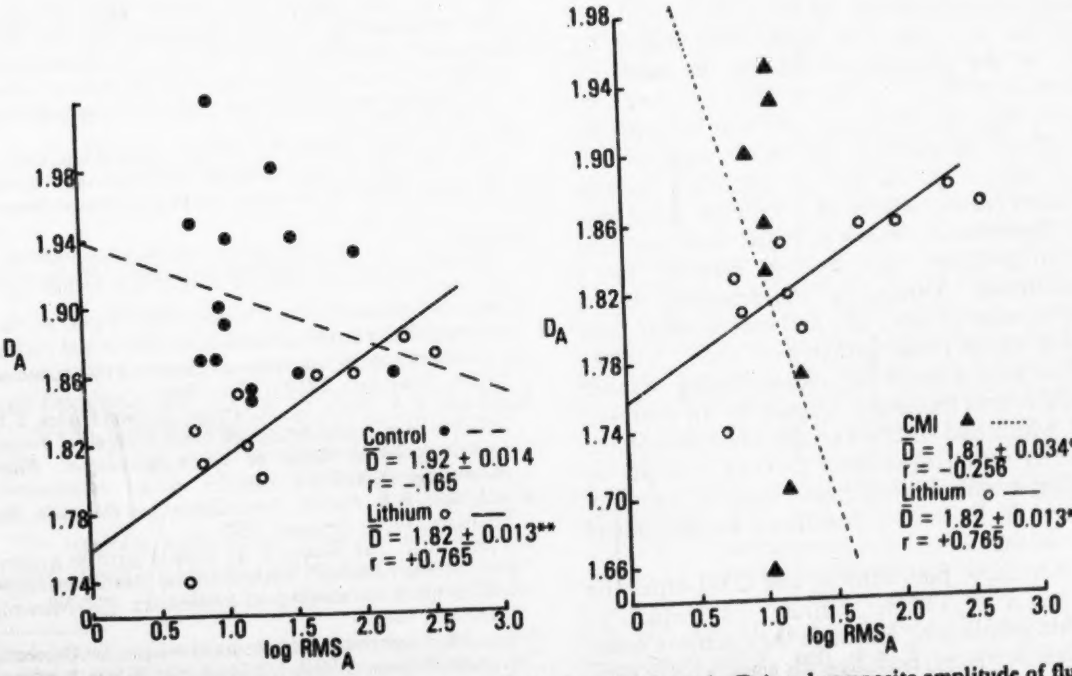

FIGURE 2. Plots showing relationship between composite frequency metric (D_A) and composite amplitude of fluctuations (log RMS_A) in control TPOH preparations and in the presence of lithium or CMI.

also changes the relationship between frequency and amplitude, as is indicated by the almost vertical regression slope. Whereas the ensemble of control points demonstrates a relatively wide range of both average frequencies and average amplitudes, lithium restricts the fluctuation frequency (most D_A values occur between 1.82 and 1.86), but CMI restricts the fluctuation amplitude across a wide range of frequency values. The mean D values, averaged for each group of experiments, indicate that both lithium and CMI significantly slow the fluctuation frequency of TPOH below the control D values of 1.92 ± 0.014.

Alternative to the long residence time TPOH assays across cofactor concentration and time (Figures 1 and 2), short residence time (initial rate) measures were performed in which the enzyme-enriched supernatant containing lithium, CMI, or neither was maintained on ice separate from the assay reactants. At 1.5-minute intervals, duplicate enzyme aliquots were removed and incubated with complete reaction mixtures for 2 minutes, yielding a series of 40 short residence determinations. The Table compares the average D_A values for TPOH activities determined in 25 separate experiments in the absence and presence of lithium or CMI. The significantly higher D_A value in the presence of lithium in these experiments (2.08 ± 0.016 vs. 2.01 ± 0.021 for control) supports the hypothesis that lithium's initial effect is to uncouple the loosely and variable phase control population of nonlinear protein oscillators (demonstrable only with the small temporal observation window of initial rates) and that macromolecular uncoupling results in a Gaussian-like population characterized by a larger number of more like and independent components which phase-gather over time (Winfree 1980) to yield a single population having reduced amplitude and frequency (Figure 2). In contrast, CMI, which had no effect on the mean fluctuation frequency of short residence kinetics, may act by inducing a more homogeneous state of coupling, reducing the variability postulated for the control preparation.

In summary, both lithium and CMI order the fluctuations of TPOH: lithium via frequency, CMI via amplitude. Although they achieve order by different routes, both ligands significantly slow the mean fluctuation frequency of the enzyme activity, altering the inverse relationship usually observed between frequency and amplitude. Short and long residence time studies suggest that different statistical mechanisms of organization of the population of nonlinear enzyme oscillators may underlie the shared and disparate effects of these two classes of drugs.

Table

Estimates of Mean TPOH Product Concentration Frequencies in the Absence and Presence of Lithium or CMI

Condition	*N* (40-Point Assays)	D_A ± S.E.M.
Control	10	2.01 ± 0.021
Lithium	8	2.08 ± 0.016*
CMI	4	1.99 ± 0.007

Characterization of Drug Effects on the EEG by Power Spectral Band Time Series Analysis[1]

Cindy L. Ehlers, Ph.D.,[2] and James W. Havstad, Ph.D.[2]

A method for quantification of the electroencephalogram (EEG) that could be used to characterize drug-influenced states in order to link them to the expression of behavior on one hand, and to underlying biochemical mechanisms on the other, has long been sought. It has been suggested that a language for coherent explanation of specific drug effects at different levels of observation (i.e., from biochemistry to behavior) may lie in the descriptions of drug-induced changes in the distribution of values around mean functions across time or across samples (Mandell 1980).

In the present investigation, the ability of five drugs that are active in the central nervous system to alter the distribution of power in discrete frequency bands of the EEG (a first-order function) was studied. In addition, fluctuations in power in those frequency bands as a function of time, i.e., the power spectral band time series (a second-order function) were evaluated in order to characterize drug effects and correlations to behavior.

The subjects were three adult male Guyanan squirrel monkeys (*Saimiri sciureus*) weighing 835 to 993 grams. Under pentobarbital anesthesia (Nembutal, 35 mg/kg) screw electrodes had been implanted previously in their calvaria in a modified 10-20 array to approximate homotopic locations over frontal and parietal cortices similar to human sites. After at least 2 weeks' recovery from surgery, the monkeys were adapted to a loosely restraining Plexiglas chair for 2 hours, two times a week for 3 months, before the drug studies were begun. The psychoactive compounds studied and their doses were: amphetamine, 0.25 mg/kg; diazepam, 2.5 and 5.0 mg/kg; phenobarbital, 15 and 30 mg/kg; chlorpromazine, 5 and 10 mg/kg; and morphine, 2.5 and 5.0 mg/kg. All were administered orally, by gastric lavage. The order and dose of each drug were randomized for each animal, and at least 5 days elapsed between drug administrations.

On a test day, a monkey is chaired briefly and administered drug or vehicle and then returned to the home cage. Approximately 40 minutes later the animal is returned to the chair and placed in the recording chamber. EEG is recorded for 20 minutes on paper (Grass Model 7D polygraph) and on magnetic tape (Vetter Model D FM recorder) for later computer analysis. The present data were analyzed from artifact-free 15-minute segments of tape from the left fronto-parietal lead (F3-C3). The processing is done by a MINC LSI-11, which digitizes and calculates the power spectra of four-second epochs in 1/4-Hz increments over a range of 0.25 to 64 Hz, a procedure similar to that first described by Joy et al. (1971) and modified by Gehrmann and Killam (1976). The transformed data are then further compressed into eight frequency bands (0.5-1.0 Hz; 1-2 Hz; 2-4 Hz; 4-8 Hz; 16-32 Hz; 32-64 Hz; and 0.5-64 Hz). Mean power density of each frequency band over the entire recording period can then be calculated. In addition, as a function of time, the fluctuations in power density in each frequency band can be displayed as a time series. The calculation of the power spectral band time series is similar to that described by Gehrmann and Killam (1978) and Gehrmann et al. (1977).

The five drugs studied were differentiated from vehicle by various distributions of mean spectral power density in the four bands: 2-4 Hz; 4-8 Hz; 8-16 Hz; and 16-32 Hz (Figure 1). In the lower frequencies (2-4 and 4-8 Hz) amphetamine caused a small increase in power, whereas diazepam caused a dose-dependent decrease.

Phenobarbital had little effect on power density in the lower frequencies. However, both morphine and chlorpromazine caused dose-dependent increases.

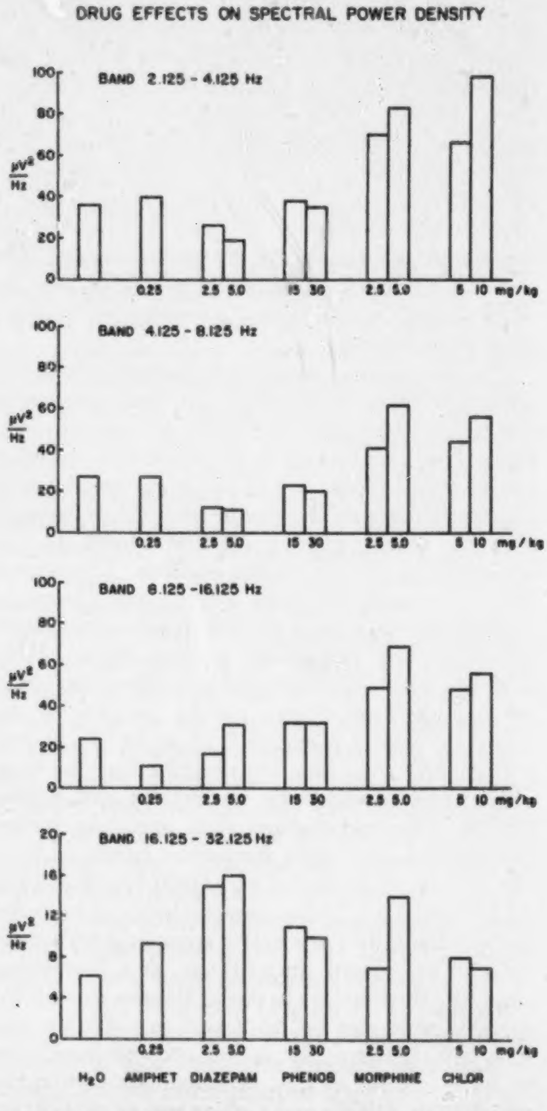

FIGURE 1. EEG mean spectral power density, μV^2/Hz, in four different frequency bands (2.125-4.125 Hz; 4.125-8.125 Hz; 8.125-16.125 Hz; 16.125-32.125 Hz) recorded from F3-C3 for 15 min in a typical monkey after oral administration of: water; amphetamine, 0.25 mg/kg; diazepam, 2.5 and 5.0 mg/kg; phenobarbital, 15 and 30 mg/kg; chlorpromazine, 5 and 10 mg/kg; and morphine, 2.5 and 5.0 mg/kg.

In the higher frequency band (8-16 Hz), which contains the posterior dominant rhythm, amphetamine caused a decrease in power. A decrease in power density following 2.5 mg/kg diazepam was noted, whereas the higher dose (5.0 mg/kg) caused a smaller increase in power in the 8-16 Hz band. A small increase in power, not dose-related, was also seen following administration of phenobarbital. Morphine and chlorpromazine both caused dose-related increases in power density. A different distribution of power was revealed in the high frequency band (16-32 Hz). Amphetamine and phenobarbital induced small increases in this band, whereas diazepam produced a dramatic dose-dependent increase. Neither chlorpromazine nor the low dose of morphine (2.5 mg/kg) caused any change in power density, but the higher morphine dose (5.0 mg/kg) caused an increase.

Analysis by power spectral band time series provided even better discrimination of drug effects which correlated well with the ongoing behavioral state of the animal. The bands that provided the best discrimination were the two representing frequencies of 8-16 Hz and 16-32 Hz. Under baseline conditions following water gavage or gavage of diazepam vehicle, all the monkeys fluctuated between a "vigilant" state associated with mild motor movement and visual scanning and a quiescent state associated with little visual scanning. This fluctuation in behavioral state was associated with distinct oscillations in the power spectra. During the more vigilant state the EEG was relatively desynchronized, concomitant with an increase in power density in the 16-32 Hz band. When an animal's behavior was quiescent, the EEG was relatively more synchronized, and power increased in the 8-16 Hz band. The oscillation in power spectral density and behavior was very stable under control conditions and was reproducibly altered by drug treatment.

In Figure 2, a distinct difference in the power spectral band time series is obvious after 2.5 mg/kg diazepam. A decrease in the dominant frequency of oscillation and the appearance of a higher frequency fluctuation are associated with a more quiescent behavioral state. A more random pattern of high and low frequency components is seen after 5.0 mg/kg diazepam and associated with mild sedation. A behavioral state and time

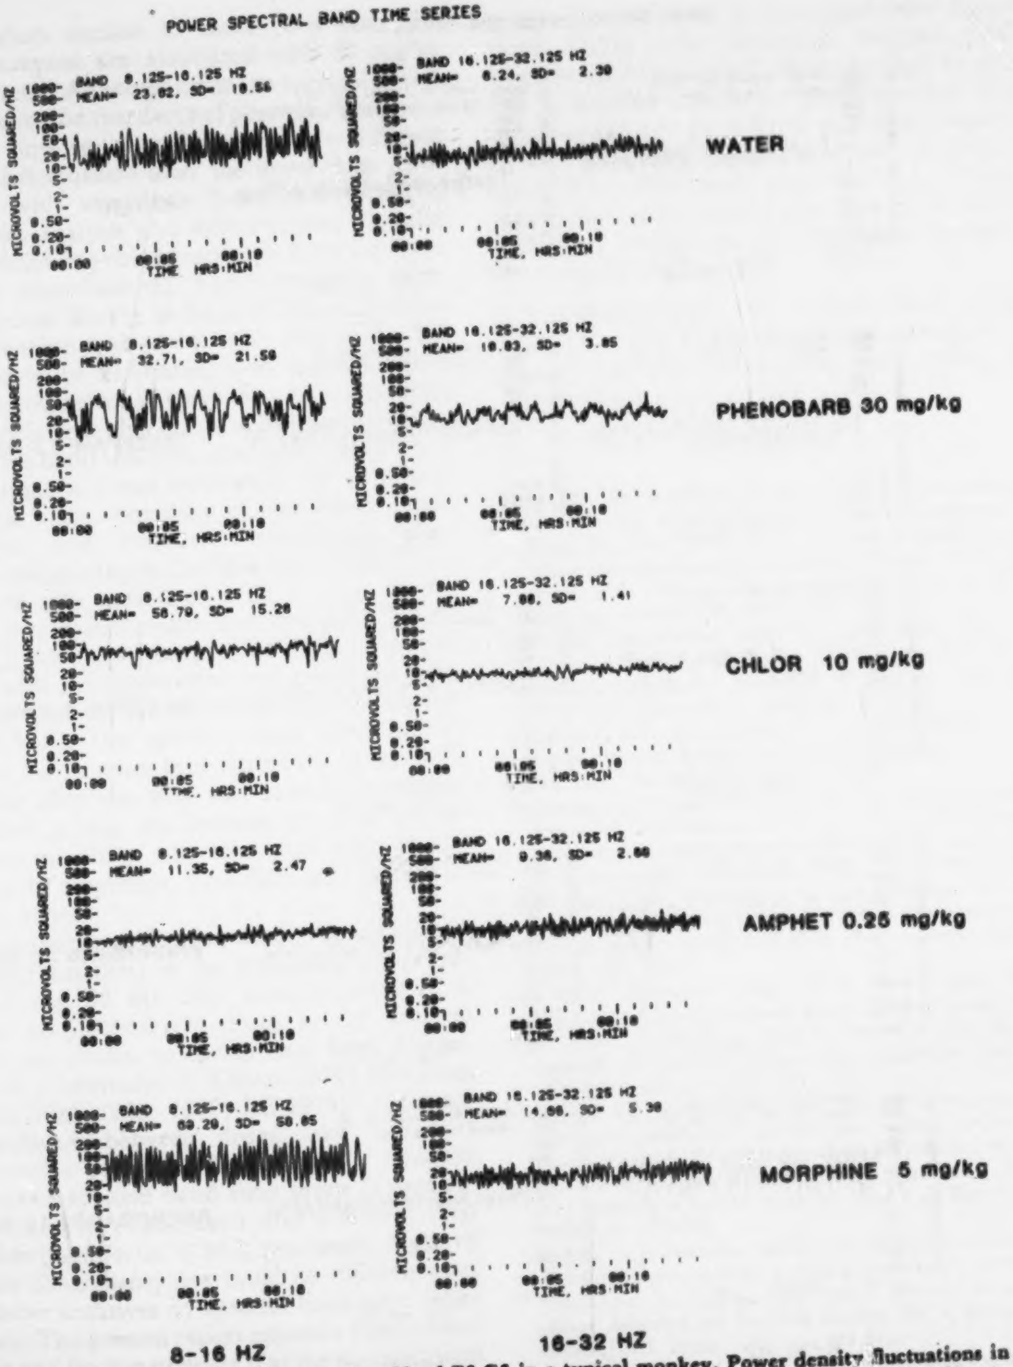

FIGURE 2. Power spectral band time series of lead F3-C3 in a typical monkey. Power density fluctuations in bands 8.125-16.125 and 16.125-32.125 Hz are presented from EEG recorded after oral administration of: water; diazepam, 2.5 and 5.0 mg/kg; and phenobarbital, 15 and 30 mg/kg. For each time series, power density ($\mu V^2/Hz$) is represented on the ordinate, and time (minutes) is represented on the abscissa.

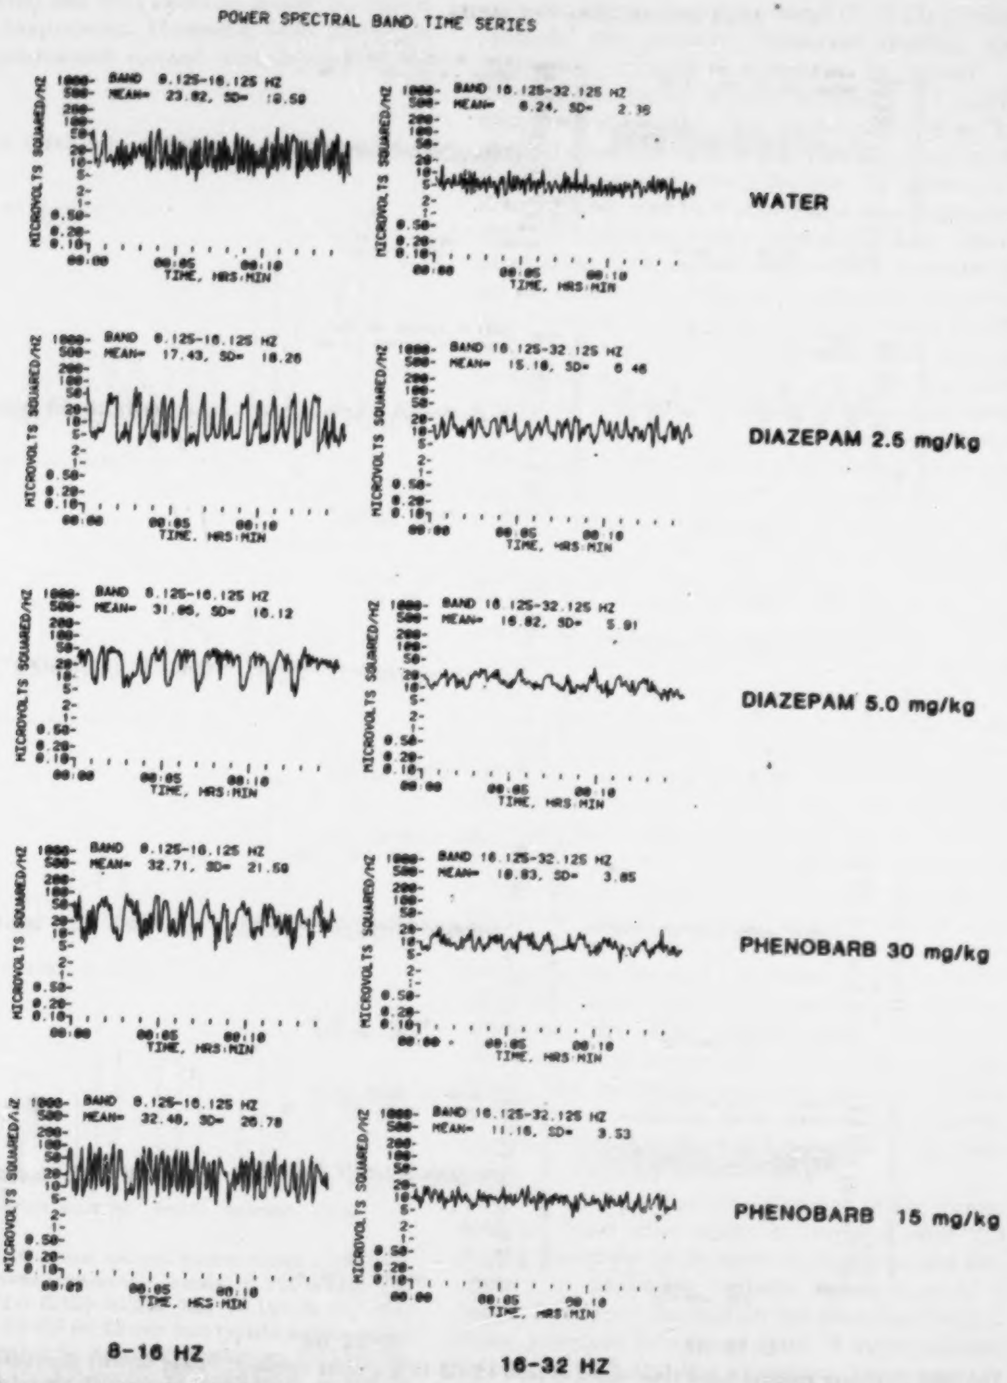

FIGURE 3. Power spectral band time series of lead F3-C3 in a typical monkey from EEG recorder after oral administration of: water; phenobarbital, 30 mg/kg; chlorpromazine, 10 mg/kg; amphetamine, 0.25 mg/kg; and morphine, 5.0 mg/kg. Coordinates are the same as in Figure 2.

series pattern similar to those seen after 5.0 mg/kg diazepam are associated with 30 mg/kg phenobarbital. Although the mean spectral power densities after the two doses of phenobarbital were identical, time series analysis reveals a different pattern of fluctuation after the lower dose, concomitant with very little behavioral sedation. Time series analysis also differentiated the mild sedation following chlorpromazine from that produced by phenobarbital. The increase in mean power spectral density in the 8-16 Hz range from chlorpromazine produced a stable time series that contrasted to the less stable, more random signal after phenobarbital (Figure 3). A stable time series associated with a decrease in mean power in the 8-16 Hz band was seen after administration of amphetamine and was associated with a vigilant behavioral state consisting of decreased motor movement and increased visual scanning, whereas the stability in the time series after chlorpromazine was associated with a state of decreased motor movement and decreased visual scanning. Although the profiles of mean power density with chlorpromazine and morphine were similar (Figure 1), the two drugs were clearly differentiable in the spectral band time series. Whereas the increase in mean power in the 8-16 Hz band after the first was associated with a stable time series, the increase in mean power following morphine was associated with an increase in the amplitude of the dominant rhythm in the time series.

Differentiable profiles in mean power density (a first-order function) in the frequency bands between 2 and 32 Hz after administration of a number of psychoactive drugs in the squirrel monkey are similar to earlier data from Rhesus monkeys (Gehrmann & Killam 1976) and from humans (Fink 1968, 1978; Itil 1974). A clearer differentiation between drugs, and one that relates well to ongoing behavior, can be achieved with power spectral band time series (a second-order function). Gehrmann and Killam (1978) and Gehrmann et al. (1977) previously reported that the benzodiazepines could be differentiated from other sedatives by spectral band time series analysis. The present report expands those observations and further suggests that the spectral band time series may be used to characterize drug-influenced behavioral states. Prigogine and Nicolis (1973) have suggested that the stability of a system is reflected in its second-order fluctuations. Using those principles, Mandell (1981) hypothesized that drug preference might be an effort to stabilize a person's "periodic order" (e.g., amphetamine) or to shift the statistical properties of one's system to a more random, less reactive state (e.g., diazepam, phenobarbital). Further studies may provide evidence to suggest that the EEG can provide an electrographic marker of such cognitive processes.

Variational and Probabilistic Aspects of Exploratory Behavior in Space: Four Stimulant Styles

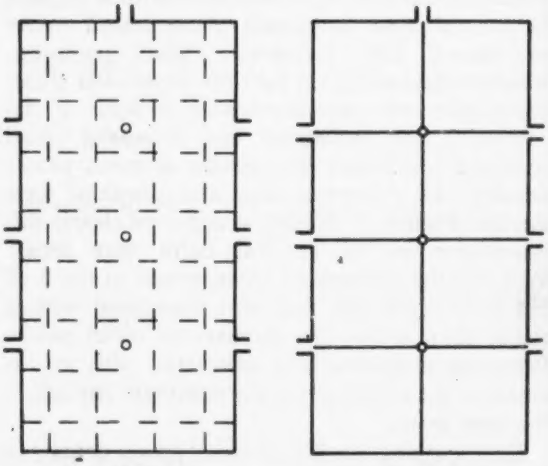
Mark A. Geyer, Ph.D.[1]

One of the primary goals of the science of Psychopharmacology is to understand and predict the effects of drugs on the molar behavior of the organism. In animal research, one of the most common behaviors of interest is spontaneous locomotor activity. This presentation describes an unusually detailed approach to the characterization of drug effects on the behavioral activity of rats in a novel environment.

While most activity measures assess only the quantity of activity—that is, activity goes up, goes down, or stays the same in response to a drug—the approach illustrated here provides both graphic and quantitative descriptions of *qualitative* differences in the locomotor activation elicited by stimulant drugs. Qualitative differences in the effects of drugs on activity are readily apparent by observation; but they may be assessed more precisely by examining variability in both the spatial and temporal domains. To illustrate the utility of measures of spatial variability, this report compares the effects of several drugs which, according to measures of the quantity of behavioral activity, are considered to be "stimulants."

Method

Male Sprague-Dawley rats (300-325 gms) were injected intraperitoneally (1 ml/kg) with either saline or the appropriate dose of one of the test drugs, as listed in the Table, 10 minutes before being placed in one of four holeboard/activity chambers for a 1-hour test session. The chamber, diagrammed in Figure 1, is a 12 X 2 inch black Plexiglas box with three floor holes and seven wall holes which serve as specific stimuli for the animal to investigate. As detailed elsewhere (Flicker & Geyer 1982), a Cartesian coordinate system of infrared beams is used to detect the position of the animal within the chamber. Each hole is also equipped with an infrared beam to detect holepokes, and a touchplate on the wall 5 inches above the floor is used to detect rearings. A microcomputer samples these circuits 10 times per second and permanently records all changes. Thus, the exact sequence of locomotor movements, holepokes, and rearings can be reproduced by the computer with a resolution of a tenth of a second in time and an inch and a half in space. The amount of activity can then be calculated as the total number of photobeam interruptions, as is done with several common activity monitors, or as crossovers from one 6-inch sector to another (Figure 1) Crossovers also measure locomotor activity.



A. PHOTOBEAMS B. SECTORS

FIGURE 1. Diagram of the holeboard box showing the ten holes in the walls and floor. (A) Dashed lines represent the 8 X 4 perpendicular array of photobeams. (B) Sectors divide the holeboard into eight 6-inch square areas. Crossovers were defined as the number of sector entries and were used as a measure of the amount of locomotor activity.

Standard Measures

The Table summarizes the basic results as hourly means for deltas (total number of photobeam breaks), crossovers, rearings, and both varied and repeated holepokes for the stimulant drugs tested. At the doses used, the various stimulants produced comparable in-

---

[1] Department of Psychiatry, School of Medicine, University of California at San Diego, La Jolla, CA 92093.

creases in the amount of locomotor activity, as reflected by the deltas and crossovers. Indeed, if these were the only measures examined, one might conclude that these drugs produce similar effects. However, even the simplest of multivariate analyses quickly dispels that notion. In contrast to the other drugs, apomorphine is unusual in that the hyperactivity it produces is accompanied by a decrease rather than an increase in both rearing and holepoking. Furthermore, amphetamine differs from the other drugs in its preferential increase in repeated holepokes into the same hole. Makanjuola et al. (1977) have referred to repeated holepokes as stereotyped as opposed to exploratory holepokes, and have also found them to be preferentially increased by amphetamine.

Table

				Holepokes	
	Deltas	Crossovers	Rearings	Repeated	Varied
Saline 1 ml/kg	1802	1289	72	44	39
Amphetamine 1 mg/kg	4706	956	138	144	95
Caffeine 6 mg/kg	4428	776	153	101	123
Apomorphine 1 mg/kg	3974	921	28	11	20
Scopolamine 1 mg/kg	4237	1001	161	54	117

1. DELTAS is the sum of all photobeam interruptions.
2. CROSSOVERS are defined as movements from one 6-inch square sector to another.
3. HOLEPOKES were divided depending on whether or not there had been an intervening rearing or poke into a different hole between two pokes into the same hole.

Spatial Patterns of Locomotion

In order to characterize the effects of the stimulants on the patterns of locomotion, one must first understand some aspects of the spatial structure of the locomotor behavior of control animals exploring a novel chamber. When the computer reconstructions of each animal's locomotor patterns are displayed on a video terminal at ten times normal speed, it is evident that each control animal is remarkably consistent in terms of the patterns of locomotion across time and that each animal exhibits a preference for one end or corner, referred to as the home area. The behavior is generally organized as excursions from the home area in which the outward path is typically more varied than the rapid and direct return path.

At the relatively low dose of 1.0 mg/kg amphetamine sulfate, the normal pattern of locomotion is disrupted. The animals rarely exhibit a home area preference and make many seemingly random changes of direction. As demonstrated by Lat (1965) and Schiorring (1979), higher doses of amphetamine produce highly stereotyped, repetitive patterns of ambulation. In contrast, a comparable dose of caffeine produces hyperactivity without altering the normal structure. Caffeine-treated rats consistently exhibit a preference for one end of the chamber, and their behavior is constructed of excursions from this end along reasonably predictable paths. Thus, hyperactivity per se need not disrupt the typical spatial structure of exploratory locomotion. Both apomorphine and scopolamine produce dramatic alterations in the locomotor patterns. Many animals treated with apomorphine persistently and rapidly circle the chamber in a consistent direction for at least 40 minutes, without rearing or investigating the holes. While other apomorphine-treated rats do not rotate, each still exhibits an individualized perseverative pattern that is maintained for an extended period. Scopolamine-treated animals also rotate around the perimeter of the chamber, rarely entering the center. However, virtually all animals given scopolamine rotate one direction several times and then reverse their direction. This characteristic pattern is maintained throughout the session, with the frequency of reversals in direction decreasing with time. Unlike apomorphine, scopolamine-treated animals frequently pause enroute to rear and/or investigate the holes in the wall.

For a variety of reasons, it was important to develop descriptive statistics with which to summarize and quantify these stylistic differences in the effects of drugs on the patterns of locomotion. To condense the data, the chamber is divided into five regions: the two ends; the center; and the two long walls. The number of each of the 16 possible transitions from one region to another is then cumulated and displayed in a two-step transition matrix as if for a Markov Chain analysis. The coefficient of variation (CV) of this set of 16 values is then calculated as an indicator of the degree to which each animal's locomotor behavior is stereotyped or perseverative in the spatial domain. For example, if an animal's locomotion were uniformly distributed about the chamber, all the numbers in the matrix would be similar and the CV would be small. Conversely, if an animal predominantly repeats the same transitions—that is, he exhibits a stereotyped pattern—the CV would be correspondingly high. Figure 2 displays 40-minute plots of the locomotor patterns of three untreated rats, together with the CVs and the total number of transitions entered into the matrix. It is important to note that, both in Figure 2 and in larger groups of animals, there is no significant correlation between the amount of activity and the degree of its spatial variability.

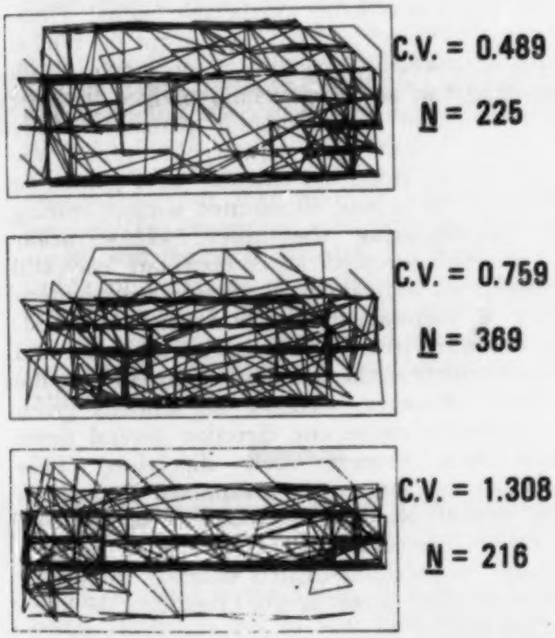


FIGURE 2. Computer reconstructions of the locomotor patterns exhibited by three untreated rats during a 40-minute session are shown together with the Coefficient of Variation (CV) and the number of transitions (*N*), as described in the text.

Figure 3 displays the group means (+/−SEM) for the CVs calculated for the hour of activity following treatment with either saline or one of the stimulant drugs. As suggested in the description of the computer reconstructions of the locomotor patterns, caffeine-treated animals are virtually identical to controls on this measure of variability, while the low dose of amphetamine produced significantly more random patterns. Conversely, both apomorphine and scopolamine significantly increased the CV, reflecting the highly stereotyped locomotor patterns induced by these drugs.

Despite the common characteristic of these stimulants in terms of their effect on the quantity of locomotor activity, each of them produces qualitatively different styles of behavioral activation which can be readily noted by observation and quantified by simple measures of spatial variability. During caffeine-elicited hyperactivity, the normal structure of the locomotor, rearing, and holepoking behaviors are maintained. With low doses of *d*-amphetamine, the spatial pattern of locomotion is randomized and repeated pokes into the same hole predominate. Apomorphine hyperactivity is unique in that rearing and investigatory holepoking are suppressed and the pattern of each animal's locomotion is highly stereotyped. Scopolamine-treated rats also exhibit a stereotyped pattern of locomotion, but one that is clearly distinguishable from that typical of apomorphine. In other studies, it has been

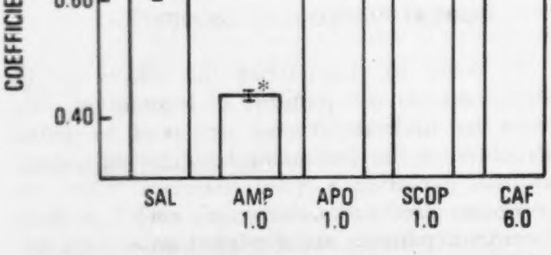

FIGURE 3. Group means (+/−SEM) are shown for the CVs (*see* text) calculated for the entire hour test session. An elevated CV reflects a repetitive spatial pattern of locomotion.

observed that significant changes in the pattern of locomotion can be detected with no change in the amount of activity (Flicker & Geyer 1982).

In the past 10 years, the field of Psychopharmacology has seen remarkable advances in the precision and sophistication of its anatomical, chemical, and physiological measures. It is clear that a similar increase in the sophistication of behavioral assessment techniques is warranted. It is hoped that the methods illustrated in this report will help to meet this need.

Heart Rate Variational Characteristics in Psychopathology: A Pilot Study[1]

Michael R. Blackburn, Ph.D.[2]

Heart rate variational characteristics in a mixed group of psychiatric patients and the changes in those characteristics accompanying pharmacotherapy were examined. The variational characteristics of heart rate may be described in terms of the magnitude of change (variance) and the temporal pattern of change (periodicity). Variance represents the responsivity or instability in a system and is calculated by taking the average of squared deviations from the mean. Periodicity as used here represents order as detected through time series analyses involving auto correlations over incremented time intervals and their Fourier transformations to the frequency domain (Jenkins & Watts 1968). A relationship may exist between magnitude and the temporal pattern of change characteristic of the system's organization. For example, Zweiner (1978) noted the general positive relationship between period length and amplitude in both heart rate and blood pressure spectra. Because the regulation of heart rate as seen in the dynamics of the interbeat interval (IBI) is, through vagal and sympathetic mediation, normally sensitive to central nervous system events, the variational characteristics of this measure may be a peripheral reflection of central processes in psychopathology. The IBI measure was chosen for study because electrocardiogram recordings are convenient, noninvasive, and generally available.

Two Holter-monitor electrocardiograms (ECG) were obtained on each of 15 psychiatric inpatients of the San Diego Veterans Administration Medical Center. The first was a baseline record taken after 1 drug-free week on the ward. The second followed from 2 to 4 weeks after appropriate pharmacotherapy. Day (between 15:00 and 18:00 hours) and night (between 02:00 and 04:00 hours) ECG samples were transcribed from magnetic to paper tapes using an Avionics electrocardioscanner. Each sample was 24 minutes in length, but was divided into three sequential 8-minute segments for analysis. Thus, each patient was represented by a total of 12 8-minute segments of ECG data. The patient's data were grouped for statistical comparisons on the basis of medication received during therapy. Five patients received the tricyclic antidepressant imipramine; five, the butyrophenone antipsychotic haloperidol; and five, lithium carbonate. Their medical and psychiatric histories were not tabulated until after the ECG data analyses were complete (*see* Table 3). The rationale for grouping patients on the basis of drug assignment was based on the assumption that the clinical psychiatrists provided the most appropriate

---

[2] Department of Psychiatry, School of Medicine, University of California at San Diego, La Jolla, CA 92093.

therapeutic agents for their patients at the time. Furthermore, it was assumed that patients within a group shared factors that differed in degree from patients in other groups and that those factors were related to the reasons they received a particular drug. These expectations are somewhat justified by previous reports of factorial symptom profiles between groups of psychiatric patients receiving different psychotropic drugs (Overall et al. 1972; Overall & Henry 1973).

A time series of heart IBIs was produced from each 8-minute segment by dividing the segment into 40 consecutive 12-second epochs, then the distance between extreme beats of an epoch divided by the number of beats contained within the extremes was used to describe the average IBI for that epoch. A representative IBI was calculated for each of the 40 epochs per 8-minute segment. The means and coefficients of variation of the segment average IBIs were computed and translated to beats per minute. For spectral analysis, the time series were first detrended by least squares linear transformation. The transformed time series were then analyzed by Fast Fourier Transform (FFT) to generate a frequency-power spectrum reflecting the relative amplitude of heart IBI periodicities in frequencies from .04 to .002 Hz (in periods from 24 to 480 seconds, respectively). The spectral peak was identified from the FFT spectrogram as the frequency (period length) with the greatest associated power. Spectral peak power was expressed as a percentage of the total variance of the underlying time series. Results from the spectral analyses of the three 8-minute segments per subject within a condition (for example, baseline day) were averaged to increase within-subject reliability. Analyses of variance were performed on these averaged values. Within-subject correlations of spectral peak period and spectral peak power were computed with the results from analyses of the 8-minute (unaveraged) segments over all conditions (N = 12 per subject). Fisher's Z transformations of the correlation coefficients (Zar 1974) were tested by analysis of variance for group differences. The 5 percent level of statistical significance was tested throughout. All calculations except the analyses of variance were performed on a Burroughs 7800 computer using the International Mathematics and Statistical Library program packages in Fortran.

The three groups differed over all conditions on the measures of heart rate and its coefficient of variation (Table 1A). Heart rate was lower in the haloperidol group than in the other two groups, and the coefficient of variation was lowest in the lithium group. With the groups combined, heart rate was reduced at night, and the spectral peak power decreased at night (Table 1B). The only difference between baseline and drug conditions was a decrease in spectral peak power in the drug condition (Table 1C). Thus, both night and drug therapy conditions were accompanied by reductions in periodicity of heart rate change defined by reduced peak power. There were no interactions between the conditions or between the conditions and the groups. All three groups responded similarly to any change in the condition.

The measures of spectral peak period and spectral peak power were generally correlated in the imipramine and lithium groups, but not in the haloperidol group (Table 2). The positive correlation indicated that there was a linear relationship between period length and the signal-to-noise ratio of the periodicity; that is, when the spectral peak was located at the slow end of the spectrum, it tended to have a higher amplitude relative to the sum of the other variations in the record than a spectral peak located at the fast end of a spectrum derived from other data. In the haloperidol group, periodicity could not be predicted from the location of the period with the greatest amplitude in the spectrum.

Table 1

Average Values of Dependent Measures by Group and Condition

Comparisons	Heart Rate		Spectral Peak	
	Level	Variation[a]	Period Length	Power
A) Imipramine	84.3 bpm	0.052	195 sec	17.4%
Haloperidol	71.3*	0.061	199	16.5
Lithium	84.3	0.035*	162	16.7

The reduction in spectral peak power with pharmacotherapy is interesting because periodicity has often been associated with pathology (Glass & Mackey 1979). For example, in fetal monitoring during labor and delivery, a sinusoidal heart rate pattern was indicative of fetal distress (Rochard et al. 1976). A similar heart rate pattern was seen in neonatal hypoxia (Reid et al. 1979). Adult obstructive sleep apnea with periodic hypoxia was also accompanied by heart rate periodicity (Tilkian et al. 1977), as are other cardio-respiratory disorders such as Cheyne-Stokes respiration (Dowell et al. 1971) and chronic heart failure (Mantle et al. 1978). Examples of increased periodicity in heart rate were found for psychosomatic disorders (Zweiner 1978) and in oxygen saturation for schizophrenia (Lovett Doust 1980).

In both normal and abnormal cases, heart rate periodicity is usually related to respiration. The respiratory sinus arrhythmia accounts for a large part of the heart rate variation in periods less than 12 seconds in length (Luczak & Laurig 1973; Penaz et al. 1978). The contribution of respiratory sinus arrhythmia was eliminated in the present study by averaging IBIs over 12-second epochs to define each datum point. Sleep apnea could have contributed to the spectral peaks in the 24- to 480-second range, but probably did not because periodicity was reduced at night. Thus the periodicity in this group of psychiatric patients may be unrelated to respiration in the reported range, but reflect disturbances in other central systems. The interpretation of periodicity as abnormal depends, however, on its inappropriateness for the organism's adaptation. Periodicity may be considered pathological to the extent that it reduces the range of potentially adaptive variations. For example, autonomously periodic behavior captured by internal rhythmic mechanisms may become dissociated from environmental events and appear as stereotypy, compulsions, or paranoia. Halberg (1969) suggested that the alteration of periodic processes or the occurrence of periodicity in aperiodic processes may accompany or contribute to disease. If that is so, the restoration of original system variational characteristics may be a requirement for the return to health. This study has not directly demonstrated a change in variational characteristics with disease states, but it has indicated that periodicity may be reduced if the disease signs are ameliorated. Thus the normal condition can be predicted to be one of sensitive instability that allows the organism to respond adaptively to environmental change.

The positive relationship between period length and amplitude is commonly found in many measures, most notably the electroencephalogram, but the haloperidol group is noteworthy here in its failure to develop reliable correlations on these two heart rate variables. The certainty of the uniqueness of the haloperidol patients is reinforced by an examination of the patients' psychiatric classifications in Table 3. Of seven cases with research diagnostic criteria (RDC) indicative of schizophrenia, four were given haloperidol; two received lithium; and one received imipramine. Six of those seven had insignificant correlations of peak period and peak power. Thus the pathology of schizophrenia may involve mechanisms that disrupt the organization of central periodic processes. Neither the average peak location nor the average peak power were different between the haloperidol group and the other two groups. Therefore the distribution of power was no more random within individual spectra, but power did tend to be randomly distributed among the peak frequencies between spectra. This suggests that the haloperidol patients experienced not only periodic central disturbances but that there were inconsistencies in the contributions of these periodic processes. The inconsistency may result in a cognitive and emotional confusion characteristic of schizophrenia. The major psychoses may share the tendency for the central nervous system to become trapped in

Table 3

Characteristics of Sample

Medication Group	Subject	Age	Sex	Race	RDC*	Psychiatric and Medical Notes

*Research Diagnostic Criteria (Spitzer, Endicott, and Robins)

limited modes of function, which modes could differ among the psychoses. Schizophrenia could then be further compounded by an instability between modes, differing from normal in the duration of their fluctuations and consequent inappropriateness to the environment.

Summary

Periodicity of heart rate change in a mixed group of psychiatric patients was found to decrease both at night and subsequent to pharmacotherapy. This finding is consistent with an interpretation of emergent periodicity as a sign of disease and could represent a brain state with limited capacity for adaptation. A subgroup of patients who received haloperidol as part of their indicated treatment during hospitalization was characterized by instability in a function governing rate changes. This instability could represent chaotic central nervous system processes that are manifested in confused cognition and inappropriate affect.

Acknowledgments: The author wishes to thank Dr. Leighton Huey for providing patient data, Patrick Russo for assistance in data analysis, and Dr. Arnold Mandell for direction and discussion.

Attending or Discriminating 40 Hz Modulated Tones Induces Phase-Locked Subharmonic Resonances in EEG

Scott D. Makeig, M.A.,[1] and Robert Galambos, M.D.[2]

Introduction

Recently, Galambos et al. (1981) published a study of brain potentials evoked by trains of tones or clicks at high rates, reporting that the human auditory evoked potential response shows a resonance near 40 Hz. The amplitude of this 40 Hz driven response decreases markedly in sleep. This fact, and the body of experiments linking spontaneous and evoked 40 Hz activity to cognition (Sheer 1970; Spydell 1979), suggested to the authors that the 40 Hz response might be usable to probe level of arousal. What follows is a preliminary report of an experiment designed to explore the effects of attention on the 40 Hz response.

Method

The stimuli consisted of trains of low (800 Hz), middle (1000 Hz), and high (1200 Hz) tonebursts, modulated at 40 Hz, and presented to six subjects under four task conditions — "count the low tones," "count the middle tones," "count the high tones," and "don't count."

The low and high tonebursts were relatively rare (each 12-20% of the total), and the middle tonebursts relatively frequent (60-84%). Four to eight blocks of data were collected from each subject, each block consisting of one run in each of the four conditions. Order of runs within blocks and order of tones within runs were randomized under direct computer control.

Each run lasted about 100 seconds and consisted of 96 tonebursts. Each toneburst consisted of ten tone pips (duration 5 msec), with an interpip interval of 25 msec (onset-to-onset). Each tonepip was composed of four, five, or six half-sinewave clicks. The interval between tonebursts was approximately one second (onset-to-onset), with 200 msec of random jitter introduced in inter-burst intervals to avoid phase-locking to ongoing electroencephalograph (EEG) rhythms.

Subjects were seated with eyes closed in a quiet room. Stimuli were delivered to the right ear at 30 dB above threshold. Subjects reported the task to be difficult, owing to the low level of the signal, the small differences between frequencies, and the necessity of sustaining attention throughout the 2-minute runs. Four channels of evoked responses were collected using Grass EEG amplifiers (bandpass 3-300 Hz) and a Nicolet averaging computer. Results from the bipolar derivation (Cz-Oz) are reported here.

Results

The top two traces of Figure 1 show the averaged (Cz-Oz) responses of one subject to the same

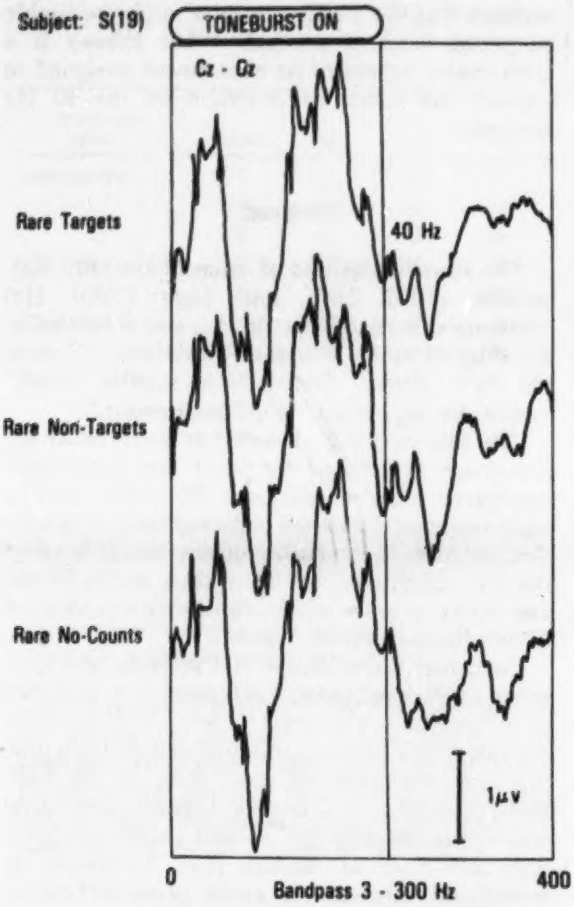

FIGURE 1. Average responses to rare targets (top trace), and rare non-targets in the "count high tones" and "count low tones" conditions (middle trace). Bottom trace is the response to the rare tones in the "don't count" condition. Each response is the sum of responses to about 200 tonebursts, in a total of eight blocks of trials over 80 minutes. The thin downward spikes in the responses during the time the toneburst is on are stimulus artifacts. (In these figures Cz positive is upward.)

stimuli (high and low tonebursts in the "count highs" and "count lows" conditions), segregated into "rare target" and "rare nontarget" responses. ("Rare nontargets" are the high tones in the "count lows" condition plus the low tones in the "count highs" condition.) The bottom trace is the responses to these same stimuli in the "don't count" condition (the "rare no counts"). Note in each of these traces the circa 1 μv 40 Hz modulation superimposed on the slower evoked response by the 40 Hz modulation of the toneburst.

The differences between pairs of the three responses shown in Figure 1 are seen in Figure 2. The (target-nontarget) and (nontarget-no count) difference waves each show a regular oscillation at circa 20 Hz which becomes locked in both frequency and phase to the moments of occurrence of tone pips within the toneburst (i.e., to multiples of 25 msec), and continues to at least the end of the sweep (400 msec after onset). A similar 20 Hz characteristic may be seen, less distinctly, in the (target-no count) comparison (Figure 2, bottom trace).

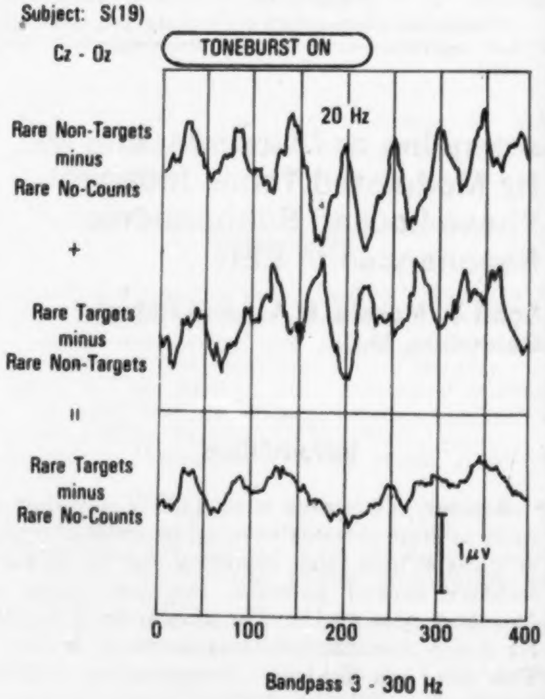

FIGURE 2. Difference waves between pairs of the three responses shown in Figure 1. Vertical lines are drawn every 50 msec. Note the progressive frequency and phase-locking of the difference waves and the stability of this phase-locking after offset of the toneburst.

Figure 3 shows the same difference wave comparisons for a second subject. Here frequency-and phase-locked rhythmic difference waves are also evident—but for this subject they are locked predominantly to about 10 Hz.

The (target-nontarget) comparisons for two other subjects are shown in Figure 4. Rhythmicities at about 13 Hz are evident (i.e., at about 1/3 of 40 Hz). In further experiments, evoked rhythmicities at 26 and at 32 Hz (2/3 and 4/5 of 40 Hz) have also been seen. However, rhythms evoked at frequencies other than 10 and 20 Hz have not been seen to "ring" on after toneburst offset, as do difference waves at 10 and 20 Hz (*see* Figure 4).

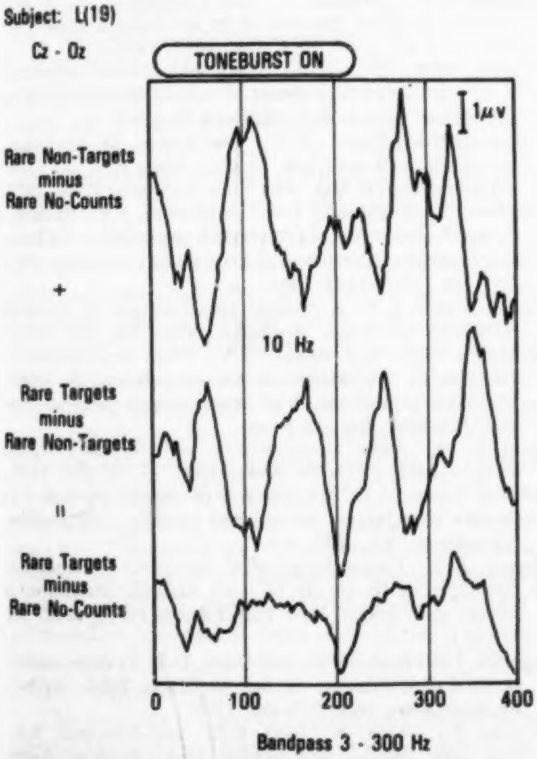

FIGURE 3. The same difference waves as shown in Figure 2 for another subject. Note again the progressive frequency- and phase-locking of the difference waves and their amplitude stability, in this case showing a 10 Hz characteristic.

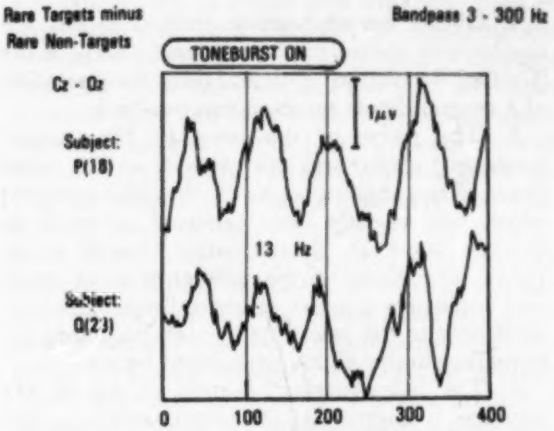

FIGURE 4. The target-nontarget comparisons for two other subjects who show a circa 13 Hz characteristic during the toneburst.

Tentative Conclusions

Results of these first experiments suggest:

1. Difference waves between responses evoked by target and nontarget 40 Hz-modulated tonebursts reveal differences in amount of nonlinear brain resonance to the modulating frequency of the bursts. These rhythmic difference waves reflect differences in task-relevance of the stimuli, and thus are a new class of endogenous cognitive evoked response, possibly related to the event-related rhythmicities (ERR) discussed by John (*see* Galambos & Hillyard 1981).

2. The rhythmic character of the difference responses seems to be most pronounced in comparisons involving *non*-targets in the "count" conditions. The authors note that similar stimulus-evoked "alpha-like" EEG activity has previously been associated with nontarget stimuli and "inhibitory" cognitive processes (*see* Morrell 1966).

3. The remarkable phase-locking and amplitude stability of the circa 20 and 10 Hz subharmonic difference waves (*see* Figure 2) may be related to the theorized relative stability of successive bifurcations in a variety of physical dynamic systems (Feigenbaum 1979), as well as to bifurcations at these same (40 Hz, 20 Hz, 10 Hz) frequencies reported in various psychophysical (Kristofferson 1980; Augenstein 1955) and electrophysiological (Barnett et al. 1971; Freeman 1961, 1962) experiments.

4. Of the few derivations studied so far, the rhythmic characteristic is seen most clearly in the (Cz-Oz) derivation. This suggests the operation of a central dipole oriented front-to-back.

5. The phase of the circa 10 Hz (target-nontarget) differences corresponds to the same phase of the ongoing alpha rhythm (Oz-positive) which has recently been reported to result in quickest two-flash discrimination (Varelo et al. 1981). The phase of the difference wave could thus indicate a process of central modulation of sensitivity to the intermittent high-frequency information in the 40 Hz modulated bursts.

6. The "after-ringing" portion of the 40 Hz response is augmented for targets and attended tones in some subjects, but not augmented in others.

7. While the degree of stability of these responses within subjects has not been fully assessed, within the sessions reported here these responses seem to be remarkably stable, save perhaps in the "don't count" condition.

Discussion

The authors plan systematic investigations of the range and stability of the responses, and on the effects of changing modulating frequency and modality of the stimuli. They also intend to explore the relation of these phenomena to the endogenous responses (N1, P3, N4, etc.) seen in experiments using unmodulated stimuli (Hillyard et al. 1978).

The present evoked rhythmicities may bear some relation to the harmonic nonlinear phenomena seen in transition to turbulence of driven responses in physical (Feigenbaum 1979; Keolian et al. 1981) and biological (Mandell & Russo 1982) systems. Their range is similar to the variety of harmonic responses to photic driving seen in the raw EEG by Mundy-Castle (1953) and Fukushima (1975). They may also relate to the body of psychophysical theory and experiment relating to "perceptual moments" and "excitability cycles" (reviewed in Harter 1966). While these results are not yet thoroughly tested, they renew interest in exploring the role of nonlinear resonant brain dynamics in cognition.

Nonlinear Dynamics in Brain Processes[1]

Arnold J. Mandell, M.D.[2]

Universal patterns of behavior, often claimed for human personality syndromes described in the psychoanalytic language of instinct and defense, may be defined and explored more rigorously using global properties of the structure of solutions to N-dimensional nonlinear differential equation sets representative of the behavior of an open, complex interactive system, i.e., the brain. Two conceptual approaches, irreversible thermodynamics and dynamical control theory, make different assumptions concerning the critical determinants of these emergent forms.

Freud lived at 19 Berggasse, "half way up the street" between the homes of the poor below and those of the independently wealthy with higher house numbers (Engelman 1976). The new machines of the Industrial Revolution running on the closed system thermodynamics of Carnot cycles and the Darwinian survival theme of private entrepreneurship were certainly consistent with an energy-dependent psychoanalytic ordering principle of "needs" and their fulfillment. Structure emerged from this dissipation. Energy also drove the fluctuations of the linear, time-dependent diffusivities of Brownian motion (Einstein 1905) that brought an unexpected degree of predictability to randomness for Freud's contemporary Einstein who, working for barely adequate wages at a patent office was, in a way, also "half way up." The need was for survival, and it was attended by a fear of nonlinear unpredictability. Heroic attempts were made to derive N-particle probability densities from functionals of one-particle systems in moderately dense gases—without success.

The dominant turn-of-the-century theme of required energy might explain why the work of two contemporaries of Freud and Einstein, Jung in psychoanalysis, and Poincaré in mathematical physics, was relatively ignored. Jung's message came not from the brainstem but from the upper shakras: myth and form better represented man's supramolecular order that (once fed) organized all the rest (Jung 1956). Poincaré said that given the fact that things were moving already, the constraints (laws) of nature derived not from limitations on activation energy required to get out of a potential well, but restrictive features of interaction; for example, a thing cannot stand on a place that is already occupied. When more than two things are closely engaged, it is difficult to know what comes next with respect to specific predictive parameter values; yet topological dynamics have revealed that there are definite limitations on the number of possibilities (Poincaré 1957). When Boltzmann's dense gas became non-independent particles, even at long times, "slaving" social organization and its measurement via order parameters crept quietly into what is now an exploding physics of complex systems (Haken 1978).

Recent research confirms Kety's findings in the late 1940s that the whole brains of wild psychotic patients and normal sleeping people burn the same mean number of calories per minute (Kety et al. 1948) but are vastly different with respect to the temporal and spatial arrangements of "hot" spots (Sokoloff et al. 1981). A surface on which a multiplicity of topographies can add up to the same mean energy utilization is consistent with the statistical thermodynamics of an ensemble of systems with a variety of entropic "styles" of information transport whose phase relations, couplings, not available fuel, are deterministic with respect to measures of thought, feelings, and action. These ruling dynamical forms appear to lie somewhere between cause and effect.

At the molecular level, a similar isoenergy surface has been portrayed for the multiplicity of hydrogen (proton) configurations on protein macromolecules which determine their electromagnetic moments and therefore their pattern of interactional cooperativity (Kirkwood & Shumaker 1952). Genetic differences in an enzyme can be expressed in altered amino acid sequences away from the active site, leading to no loss of catalytic activity but alterations in the structural stability of the protein associated with changes in its regulatory properties and time-dependent patterns of variation in biosynthetic activity (Knapp et al. 1981). These characterizations are not about *what* or *how much*, but about style.

[2] Department of Psychiatry, School of Medicine, University of California at San Diego, La Jolla, CA 92093.

Poincaré's global, geometric, qualitative approach to dynamical systems offers no natural system of coordinates. The portrait of the equation set fills the entire phase space, changing with every turn of the parameter knob; an evolutionary scenario which itself becomes the mathematical object of interest. Surprisingly, qualitative aspects of local, parametized vector space, for example, the stability of the motions of a regional flow near a critical point, may generalize to the entire system (Abraham & Marsden 1967). Psychiatrists knew this already: the obsessional reveals the characteristics of his dynamical brain system in all that he does—from choosing what color socks to wear in the morning to eating each vegetable separately on his dinner plate—all preserving the characteristic symplectic structure of his manifold. The tails of the distribution of values around the mean for any measure reveal a mix of expanding (hysterical) and contracting (obsessional) motions leading to individually unique routes of convergence to invariant measures. Perhaps this reveals the same entropic property seen in statistical physics as characteristic relaxation times or wavelengths of the complex system's spontaneous fluctuations.

Looking through time down the manifold of the mean, attention is paid to the quality of the dynamical activity around it. The Reynolds decomposition of flow separates the average velocity from its varying part. When the graph of a deterministic two-dimensional graph of x causing f(x) is cut transversely, there are distinctive patterns in the surrounding foliage made of what used to be called error. Those in psychiatry are interested in such things: the *hows* that ride on the *whats*, the patterns of variation around the mean, the hetero- and homoclinic orbits that develop around saddle nodes seen in transverse sections, distinctive personality styles that reveal themselves in doing routine things, the process not the content of what goes on in psychotherapy hours.

Quantitative study of these qualities has evolved a variety of useful and closely related abstract metrics: eigenvalue indices of stability; critical exponents describing expansions and contractions of flows; Lyapounov characteristic exponents; geometric and topologic dimensionality; rate of information change; autocorrelation and correlation lengths; probability density distributions, especially the higher moments; phase space topology and geometry; the morphology of transverse sections; and frequency (power) spectra. Symbolic dynamics describe pattern generation and recognition beyond the state space specifics. Those in psychiatry are in search of just such schemes.

The following is a brief example of a characteristic style of evolution by several complex brain systems under repeated perturbation; the transition from a quasi-stable equilibrium to autonomous, limit cycle rhythmicity that might loosely be called a Hopf bifurcation.

Data from a study of single frog muscle endplate potentials before and after prolonged nerve stimulation (del Castillo & Katz 1954) were digitized and the values expressed as deviations from the mean voltage level (Figure 1). Spectral analysis of the frequency of variation around the mean in these intracellular recordings of random activity shows that the unimodal population, manifesting a single prominent spectral density (top graph and spectrum), split into two subpopulations with the development of response inhibition (bottom graph and spectrum). See Mandell and Russo (1981) for the statistical methods used.

The local anesthetic quinacrine which, like prolonged nerve stimulation or contact with cholinergic agonists, induces a desensitized state [as procaine does Marty (1978)] also binds cholinergic receptors and emits fluorescent noise. Analysis of these receptor fluctuations from the data of Grünhagen and Changeux (1976) reveals a similar dynamical progression (Figure 2). The control at a low drug level shows a single statistical (not limit cycle) spectral peak and associated autocorrelation length. As the system lost its response to the cholinergic agonist—an increase in sodium conductance by a *Torpedo marmorata* electric organ microsac—the spectrum reflected a change from equilibrium behavior to rhythmic "bursting" of a subpopulation observable in the undamped periodicity of the graph of the autocorrelation function. Figures 1 and 2 demonstrate the similarity in statistical manifestations of desensitization in membrane-conductance and receptor motional processes: the birth from a single population in an (average) equilibrium state of a subpopulation in a limit cycle associated with habituation of the response. After bifurcation there is fast, spontaneous rhythmic activity in a coherent subpopulation, a speculation confirmed by a recent report of the "burst" kinetics of desensitized cholinergic membrane preparations (Sakmann et al. 1980).

At the next level of neurobiological complexity, polysynaptic spinal cord flexor reflexes, an examination of the distributions of interspike intervals in spinal cord interneurons during response habituation, from the work of Groves and Thompson (1973), shows that the interneurons that were capable of a progression from sensitization to an inhibited response after repeated stimulation manifested an initial single population distribution (Figure 3, S), but those that only habituated (Figure 3, H) manifested a multiplicity of frequency-labeled populations (or the phase-locked spontaneous activity of a subharmonically bifurcating chaotic attractor).

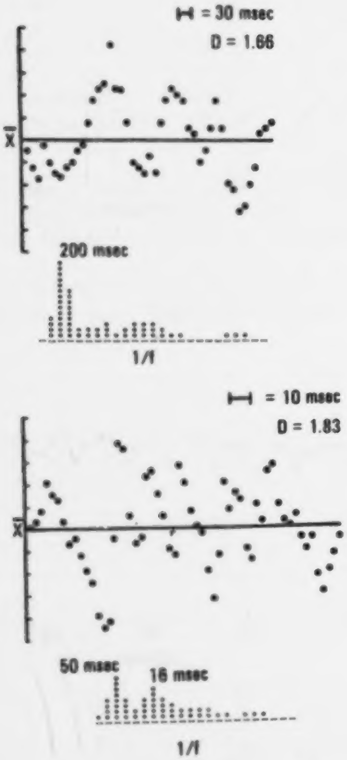

FIGURE 1. Spectral analysis of frequency of variation around mean intracellular recording of "random" endplate potentials before and after prolonged nerve stimulation, showing population bifurcation associated with response inhibition. *See* text.

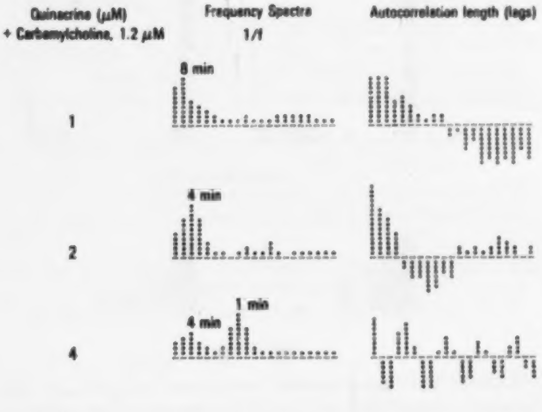

FIGURE 2. Spectra and autocorrelation functions showing shift from equilibrium behavior to subpopulation "bursting" associated with loss of response to cholinergic agonist in a population of cholinergic receptors. *See* text.

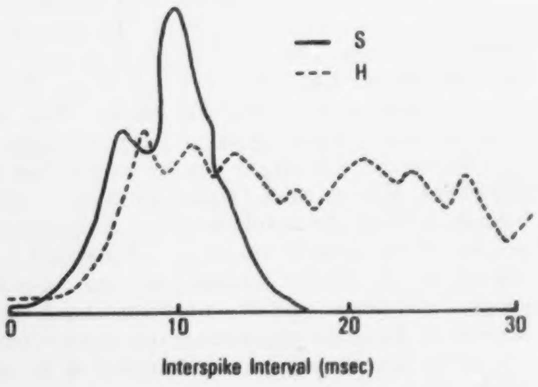

FIGURE 3. Distributions of interspike intervals in spinal cord interneurons during response habituation, showing distinction between those that manifested a single population distribution and those that contained a multiplicity of frequency-labeled populations. *See* text.

pages tightly bound

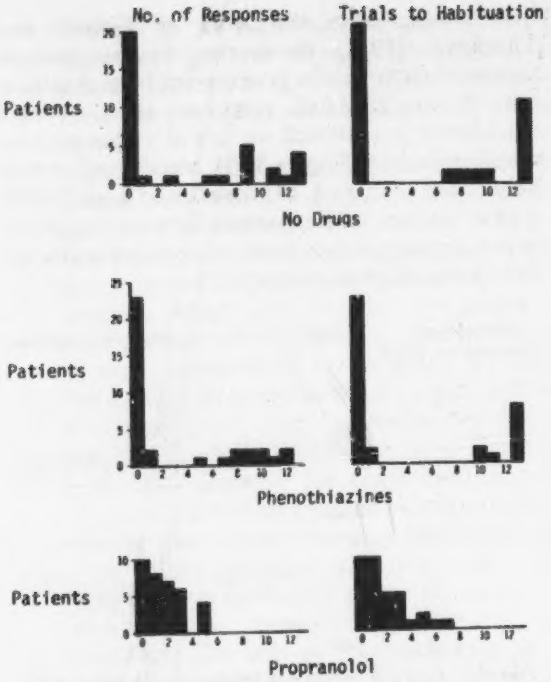

FIGURE 4. Characteristic response irregularity and failure of some schizophrenic patients to habituate an autonomically mediated skin conductance response to tones (Gruzelier 1978), showing the contrasting effects of phenothiazines and propranolol on those responses.

In Figure 4, data from Gruzelier (1978) show the characteristic response irregularity and failure of some schizophrenic patients to habituate an autonomically mediated skin conductance response to tones. The defect was not corrected by phenothiazines, but was normalized by either d- or l-propranolol (Gruzelier 1979). That the d-isomer was as effective as the l-isomer suggests that β-receptor blocking is not the mechanism of this effect. Recent work (Figure 5) suggests that both d- and l-propranolol can phase a significant portion of the kinetic variations of nigrostriatal dopaminergic tyrosine hydroxylase into a strong single rhythmic peak—perhaps coupling previously disparate populations into a more harmonically functioning whole (Mandell & Russo 1981).

It would be interesting indeed if the split-mind implied by the name of the schizophrenic syndrome were, in some cases, from a dynamical systems point of view, literally correct. It was Pavlov (1928) who first saw the deep relationships among the post-habituated state of "internal inhibition," the chronic "inhibitory condition" of schizophrenic patients, the functional cortical hemispheric splitting involved in dissociative phenomena, and the schizophrenic syndrome as resulting from the "destruction of the normal unification of the activity of the whole cortex."

It is hoped that this example suggests that the present era of qualitative mathematical description of the behavior of complex and dense systems promises a language for a scientifically based attempt at the fusion of clinical psychiatric phenomenology and neurobiological mechanism. Especially exciting is the possibility that infinite dimensional control and state spaces may be characterized by measures of low dimensional dynamical structure.

Interaction Among Government, Industry, and Extramural Investigators: New Developments and Problems

An Investigator's View

Arthur Rifkin, M.D.

The purpose of this study group was to discuss problems and solutions in the interaction among government, industry, and investigators in the development and clinical testing of new drugs, and in the evaluation of the results of drug research. Different opinions exist among these groups about the balance between scientific purity and clinical exigencies, the government's role in promoting or directing the development of drugs, and other issues involved in characterizing new therapies.

The aim was not merely to air dissatisfaction, but to state what the problem was and what should be done about it. The most optimistic expectation was that a consensus on some issues which may influence the future policy would be reached.

In recent years the protocols coming from the drug companies have been much more sophisticated in methodology, an improvement investigators welcome. This results from the growing recognition that approval of new drugs or new indications for old drugs should hew to a higher standard than before. One can usually date a clinical trials paper by its methodology alone as optimum technique changes. For example, the need to define diagnosis by atheoretical operational criteria, and to define relapse and remission in equally empirically operational terms, methodology absent in the most elegant of early studies, are now accepted as necessary. The usual competitive drives of the three players in this field—industry, government, and investigators—have combined to pursue excellence. The investigator wants his work to be believed and to be influential. To accomplish this, he must impress his peers with the adequacy of his methodology and the data analysis. How discouraging it is to be faced with a challenge to data and conclusions after months to years of work because of what others consider flaws in design or analysis. It is clear that the investigator has an interest in the tightest methodology and data analysis.

The drug company's interest, let us assume nothing more than unbridled capitalism, is to sell its product. To do this it needs a good drug to sell, it must convince the FDA of its safety and efficacy, and it must persuade the physician to prescribe it. The cost of developing and promoting a drug is enormous. It must be in the interest of the company to assure itself that its new drug or new indication is really going to work. Too often persons outside of the industry focus on its marketing aspect, which is far removed from scientific issues and easy to ridicule. They wonder if the rose of Ludiomil will sell better than the butterfly of Sinequan. Marketing aside, however, the first question facing those in the corporate boardrooms is whether the drug really works and is reasonably safe. Only if that question is answered affirmatively can they go forward and consider questions of marketing. Therefore, it is in industry's self-interest to encourage the use of the most accurate methodology and data analysis.

The third leg of this tripod, the FDA, also has its vested interest in clinical accuracy. So then, if everyone is interested in the best methodology, where is the problem?

There are some divergent interests among these groups. On the industry's side, they want as smooth sailing as possible once they are convinced that the drug works and that it is marketable, and they chafe at bureaucratic restrictions. They pressure investigators to live up to FDA standards even if they think them excessive in order to facilitate approval. The FDA is not interested in the drug company's profit, but only in protecting the public from ineffective or unsafe drugs, so they are interested in the most pure methodology.

The investigator has a responsibility shared by none of the other two partners in bringing new drugs out: he must take care of a sick person. Most improvements in methodology have been at the expense of the ease of following usual clinical procedures. In "the bad old days," making a diagnosis did not require laboriously completing scales such as the Schedule for Affective Disorders and Schizophrenia (SADS), and counting off symptoms, and making sure that all raters understood clearly and equally the distinction between thought insertion and delusions of reference. The rating scales are longer and are used more often. Diagnostic distinctions are much more careful. We are much more likely to bother the patient with requests for body fluids. All these techniques cost something that is often not apparent to those not on the firing line of obtaining data. They cost the acceptance and compliance of the patient. Without research subjects, this whole enterprise founders, so the investigator is in the position of fighting back against the FDA and the drug company, who want more purity, because the investigator fears he will lose his subjects by annoying them too much. In these days of declining interest in psychiatry by medical students, and in declining availability of money for training and research, the clinical investigator may be an endangered species. It somehow seems easier to do things in studies the further away you get from the patient.

Two issues have come up recently to make life difficult for the investigator.

It is becoming customary to insist that the blind psychiatrist treating the patient and obtaining the research data not learn which treatment his patient received until the entire study is completed. The reason is that if he learns, for example, that patients on Treatment A do better than those on Treatment B, that may bias his future ratings, especially if he thinks he can, or actually can, distinguish the treatments by their adverse reactions. There is some face validity to this, but consider the clinical consequences. If we are comparing an antidepressant to placebo, what does the clinical investigator do with the patient when he completes the trial? If he responded and received placebo, the clinician would not want to continue drug treatment. If he responded and received the active drug, the best clinical treatment would be to continue the drug openly and not risk relapse by switching to another drug. If the patient did not respond and received placebo, we might choose a different drug for followup care than if he did not respond to an active drug—or a supposedly active one. For example, if the experimental drug is a new tricyclic antidepressant (TCA), we might not wish to try another TCA, but switch to a monoamine oxidase inhibitor or electroconvulsive treatment.

When confronted with this problem, the investigator asks the drug company what it expected him to do with the patient who completed. The answer usually is to put completers on a moderate dose of another antidepressant. This is unreasonable. The patient who had responded to the experimental tricyclic, who gets a lower dose, might relapse; the patient who had not responded to the experimental drug would continue to get a possibly ineffective treatment. The placebo patient who did respond would get a moderate dose of an antidepressant abruptly—unnecessary treatment.

A more common situation would be a comparison of a new antidepressant with a standard one. Similar problems arise if the investigator tries to keep the treating psychiatrist blind and yet able to continue to treat his patient. If the investigator switches everyone who finished the study to a moderate dose of the standard antidepressant, the following would occur:

1. The patient who responded to the experimental drug would be abruptly switched to another;
2. The patient who responded to full dosage of the standard drug would be switched abruptly to a lower dose;
3. The patient who did not respond to the ex-

perimental drug would be switched abruptly to another perhaps similar drug;

4. And, worst of all, the patient who did not respond to full dosage of the standard drug would be switched to a lower dose and face another 6 weeks of ineffective treatment.

Similar unpleasant scenarios could be given for other types of drug trials.

The only way out that this writer could devise was to abruptly switch psychiatrists when the subject finished the study, keeping the first psychiatrist blind and free to continue to treat other patients in the study, while the second psychiatrist broke the blind and received other patients as they finished the study, i.e., a two-platoon system of psychiatrists.

To do all this maneuvering for the sake of the possibility of bias, if the treating psychiatrist breaks the blind as each patient completes, seems to be an example of methodological purity exceeding its bounds.

Another way of avoiding this conflict of interest is to use blind clinical raters and unblind psychiatrists. This is possible, but not perfect: the unblind psychiatrist may adjust dosage differently if he knows he is prescribing an experimental or standard drug, i.e., he may tolerate more adverse reactions of the standard drug. It is more expensive to use clinical raters if the research must pay for both the clinical rater and the psychiatrist.

Another area of difficulty is the use in some recent protocols of the provision that if the dose is lowered, it cannot again be raised because the change in adverse reactions may tip off the blind psychiatrist to whether the drug is active or placebo, or even which of two active drugs is being taken according to differential adverse reactions. This restriction will lead to two results: the blind psychiatrist will be loath to reduce dosage knowing he can not go up again, and be left giving an inadequate dose so that the subject will perhaps suffer needlessly or drop out; or the blind psychiatrist will lower the dose and threaten the accuracy of the study's attempt to answer a clinical question because of insufficient exposure to drugs.

This is another example of trying to restrict the freedom of the investigator for the sake of purer science, but actually losing more than gaining, because the impact on the clinical situation was not adequately considered.

Industry's Response to New Drug Developments

Victor B. Slotnick, Ph.D., M.D.[1]

The pharmaceutical industry maintains an ongoing interaction with the Food and Drug Administration (FDA), clinical investigators, and academia. The following are some examples of interactions that have involved the FDA.

About 5 years ago, the company was planning to initiate a 400-patient program to assess the long-term safety and efficacy of a neuroleptic in chronic schizophrenic outpatients. The patients in this program were to be treated in double-blind fashion for 12 months. During the year of treatment, each patient was to have 10 psychometric assessments. The paperwork involved in collecting efficacy data for each patient consisted of the following: Twenty Brief Psychiatric Rating Scale (BPRS) sheets (10 assessments x 2 sheets per assessment), 10 sheets of outpatient functioning assessments, and 10 sheets of Clinical Global Impressions (CGI) assessments. The total was 40 sheets of paper for each patient.

In discussing the potential paper load with the FDA, company representatives suggested supplying one summary sheet with raw efficacy data for each patient. The FDA agreed with the proposal; however, they recommended the following: 1) that the raw data for each patient be transcribed to the summary sheet after each patient completed treatment; 2) that the senior investigator sign the raw data summary sheets after transcription; and 3) that the investigator keep the original psychometric assessments for the appropriate period of time. The volume of paperwork for each patient's case report form was thus reduced by about 80 percent.

Turnaround Time of Submission to the FDA

Over the last year or so, the company's experience with regard to the amount of time the

---

[1] Clinical Investigation, McNeil Pharmaceutical, Spring House, PA 19477.

FDA has taken to respond to submissions has been encouraging.

In October 1980, a New Drug Application (NDA) for a neuroleptic with data for about 800 patients was submitted. In January 1981 the company received a written request for additional information and a request to meet with the FDA. Company representatives met with the FDA to discuss the NDA and requested that the NDA be presented to the FDA and its Advisory Committee in April. Although there was no definitive outcome from presentation to the Advisory Committee, it was heartening to experience a review of an NDA with an Advisory Committee presentation in a period of slightly less then 6 months.

In late October of this year, the company submitted a supplemental NDA to the Division. About *10 days later,* the company received a letter from the FDA indicating that the supplemental NDA had been reviewed to a limited extent and the Division felt that the submission should be transferred from supplemental NDA status to NDA status. Although the review of the NDA is still in progress, information apprising us of the status of our submission was obtained from the FDA in a relatively short period of time.

About 6 weeks ago, the company submitted a special clinical safety report for an investigational neuroleptic to the FDA. A copy of the report was hand-carried to the FDA the morning of the day of submission. That afternoon, the FDA contacted our Regulatory Affairs personnel with questions and comments concerning that submission—a same-day response.

Requests from Investigators for Clinical Supplies

During the past several years, the company has received many requests from physicians for clinical supplies. Most of these requests have been for placebos to match oral or injectable dosage forms of the company's commercially available drugs. About 1 1/2 years ago, the company implemented a policy about such placebos: they are considered to be investigational drugs. In order to obtain placebos to match marketed drugs, an investigator is required by the company to file with the FDA and obtain an individual investigational new drug (IND) number. In general, the investigators requesting placebos have cooperated with this policy.

Compassionate INDs

A working definition of a "compassionate IND" is as follows: A request by a physician to the FDA to treat a patient who has a specific life-threatening or non-life-threatening clinical condition with an investigational drug. It should be noted that the current FDA regulations make no mention of compassionate INDs. It is a fairly safe assumption that most pharmaceutical companies represented in the audience receive a fair number of requests for their investigational drugs to be used in compassionate clinical situations.

About a year ago, McNeil received a special request from one division of the FDA concerning compassionate INDs. It appeared that this division had received many requests from individual physicians requesting to study a McNeil investigational drug in two non-life-threatening compassionate clinical conditions. Because of the increased workload for the FDA, they requested that McNeil file the paperwork for those individual physicians under the company's IND for that drug.

However, an informal survey of medical colleagues revealed that other divisions of the FDA permit physicians to file directly with the FDA in order to obtain a compassionate IND.

Although McNeil was not averse to working with the Neuropharmacology Division, the problem could have been handled satisfactorily with less burden placed upon the sponsor if the Division had given McNeil a special IND number for those compassionate studies with the provision that the IND be supplemented with those physicians wishing to use the investigational drug. In all fairness, it must be added that the Division did bend a bit. At McNeil's request they allowed a reduction of the frequency of monitoring visits by the company's clinical research support staff.

Physician-Investigator Without an Institutional Review Board (IRB)

In July of 1981, the FDA published a new regulation to the effect that physicians treating patients with investigational drugs outside an institutional setting are required to have IRB approval for their studies. Most of the clinical investigators in the audience probably do not fall into this category because of their institutional setting. However, and perhaps more commonly in areas other than psychopharmacology, many private practice physicians interested in conducting investigational drug studies do not now have IRBs available to review their protocols.

In anticipation of the above regulations, and prior to their publication in the *Federal Register,* McNeil Pharmaceutical set up and organized an independent IRB in the area near McNeil. The Spring House IRB became operational in September 1981.

The Spring House IRB, in addition to protecting the patient, serves the following purposes:

1. to make an IRB available to any private practice physician interested in conducting a study with an investigational drug protocol for McNeil Pharmaceutical;
2. to reduce the cost for the approval of an investigational drug protocol; and
3. to reduce the time required for review and approval of an investigational drug protocol.

The Balance Sheet (The Other Side of the Ledger)

Paul Leber, M.D.[1]

Alistair Cooke, the noted TV essayist, once asked a bootblack, who was on the eve of his retirement, what he had learned about life in America during the many years he had shined shoes in the corridors of New York's Grand Central Station. The man, who had immigrated from Europe as a child some 70 years earlier, said without a moment's hesitation "In America, there is no free lunch!"

The bootblack clearly understood a basic principle, not, of course, unique to American soil, that you rarely get something for nothing. It is interesting to examine how this "natural" law applies to our attempts to respond to the perceived public demand for less costly and more efficient new drug development and approval.

In general, costs are conceived in terms of either time or money. In the course of clinical drug development, costs are obviously affected by the number of subjects studied, the complexity of clinical trial design, and the task and cost of data analysis. For example, increasing the complexity of the clinical trials (i.e., adding more kinds of observations and having them made more often by several independent raters) will obviously increase costs. Moreover, the subsequent analysis of data collected from large and complicated trials will also be more difficult, more expensive, and more time consuming. Sheer numbers count, too! While it is conceivable that the cost per subject or cost per individual study may fall as the absolute numbers of patients and studies increase, it is safe to assume that, other factors held constant, a new drug application (NDA) based on 20 Phase III studies enrolling 1,000 subjects will cost more than one with 10 studies enrolling 500 patients.

Given these facts, it is not surprising that, in the face of a public mandate to reduce cost, both the Agency and commercial sponsors will consider the feasibility of reducing (1) trial design complexity, (2) the number of subjects studied, and (3) the cost of data analysis in the preapproval/premarketing phase of new drug development.

This is all well and good, but recall that there is no free lunch! Pay less; get less!

It is the author's purpose to focus your attention on the other side of the balance sheet not pass judgment on the specific items involved nor judge the relative merits of the assets and debits entered. He wishes only point out that changes in one side of the ledger require changes in another part.

First the obvious. If fewer subjects are studied during the premarketing phase of new drug evaluation, our ability to detect relatively low frequency adverse or untoward drug effects will be decreased. A quick calculation illustrates any point. To be 95 percent certain of detecting at least one example of an event which occurs at an incidence of 1 per 100 patients treated for 1 month at some effective dose level of a drug, 300 patients must be observed at that dose (or a higher one) for the month. This figure is derived assuming a Poisson distribution of rare events. For general use, a good rule of thumb is that the number of subjects studied must be equal to three times the

---

[1] Food and Drug Administration, Rockville, MD 20857.

reciprocal of the estimated event rate (i.e., 300 for an incidence of 1 per 100, 1500 for an incidence of 1 per 500).

Again, the author is not passing judgment; he is merely emphasizing that if we elect to study fewer patients before a drug is approved, one should not be surprised if a relatively common adverse event is reported during postmarketing experience which was not detected during premarketing drug trials. *Parenthetically, the FDA is well aware of this problem and is actively expanding existing and developing new postmarketing surveillance strategies and programs.*

In contrast to safety, drug efficacy is determined in an absolute sense and is thus less likely to be affected by current trends toward smaller sample sizes. Thus, sample size can only be reduced to the point that the potency of the drug (that is, its efficacy) will allow.

Experts today are, in the author's opinion, even more exacting than in the past about what kind and quality of evidence collected from controlled clinical investigations is persuasive and substantial (i.e., evidence sufficient for drug approval). Thus, a modest drug, which is only slightly more effective than placebo, may require that many more subjects be studied to establish its efficacy than a potent drug would. One caveat, the author is not speaking to the issue of the magnitude of clinical effectiveness declared clinically meaningful. Rather, his comments assume that a small mean difference observed or produced by a modest drug is clinically meaningful and that it will thus require more subjects to demonstrate the statistical significance of this mean difference than it would if the mean difference were large.

There is a chance, of course, that when cost is the determining factor, it may prove more economical to use sophisticated multivariate statistical techniques to establish statistical significance than to enroll more patients or to conduct additional trials.

One problem arises when fewer subjects are studied, however, that has not often been discussed but deserves consideration and attention.

It is far simpler to demonstrate that a drug is active and efficacious than it is to describe, in detail and with precision, for whom it should be used and under what specific conditions. You may all recall that our regulations require that a prescription drug's labeling (professional package insert) provide the practitioner with adequate directions to use the drug in the population for whom it is intended.

The fewer patients studied in the premarketing phase of drug development, the more difficult it becomes to provide detailed and precise directions for the use of the drug.

Several of you were present at the recent Psychopharmacologic Drugs Advisory Committee meeting on December 3-4. You saw the advisory committee struggle with this very issue. Although convinced that two new antidepressant drug products were efficacious, it was difficult to describe, in detail, precisely for whom and under what conditions each drug should be used. It is obvious that current diagnostic categorizations (which have become possible with advances in the understanding of depressive disease) make it even more difficult to describe drug use with small numbers of subjects and limited number of trials.

In an idealized world, with an infinite amount of time, and where money was no object, we could block subjects on every diagnostic feature of potential interest and, conducting extensive trials of complicated design, determine precisely what portion of the potential patient population should take a new drug, and what would happen to them. Then we could write very complete and accurate drug labeling. But, as the English novelist Butler suggested approximately 100 years ago, *life is the task of drawing satisfactory inferences from inadequate premises.* If we are to follow the public mandate for less costly and speedier drug approval, we may have to accept broader labeling inferences from smaller and perhaps narrower data bases. Just how much smaller and how much narrower is an issue many of you in the audience will help decide while serving in your roles as our official advisors and outside experts. The issues involved are broad and beyond those covered by law. It is clearly a matter of informed judgment how much must be known about an active and efficacious drug before it is introduced into the market place. These are the questions we will all have to answer.

It is useful to remember, too, that there "is no free lunch." If we extensively modify the new drug development process as is now being actively considered in order to expedite the development and approval process of new drugs, a complete understanding of a new drug's best use may have to come from postmarketing experience and reassessment of the drug's benefit/risk ratio. Remember, there are no absolutes in this process. Words and phrases like "well controlled" and "substantial" and "adequate direction for use" are determined by the opinion of experts as much as by law. The FDA looks forward to your careful consideration and counsel on these important issues.

New Biological Approaches to Schizophrenia

Dopamine Neuronal Instability: A Model for the Schizophreniform Psychoses[1]

Roy J. King, M.D., Ph.D.;[2] Joachim D. Raese, M.D.,[2] Bernard A. Huberman, Ph.D.,[3] and Jack D. Barchas, M.D.[2]

The dopamine model of schizophrenia predicts that an excess in dopamine (DA) causes psychotic symptoms. Such a simple excess is not confirmed by the observed behavior of schizophrenics. Bleuler (1950) noted that schizophrenic individuals often manifest rapidly alternating and mutually contradictory affect, thought, and activity. Ellinwood et al. (1974), after injecting amphetamine chronically to cats, found a desynchronization and a fragmentation of their stereotypic behavior. Moreover, experimental evidence has not revealed an increase of dopamine function in schizophrenics. The authors propose here that, rather than an excess of DA, psychotic individuals exhibit an instability in dopaminergic function. This instability would be caused by an excessive dopaminergic feedback. Since the dopaminergic system appears to be well modulated with a variety of feedback mechanisms, including long-loop neuronal feedback, short-loop local inhibitory feedback, and regulation of dopamine synthesis through the activation of tyrosine hydroxylase, these mechanisms may be more crucial in determining psychotic symptoms. It is well know that systems with a high degree of negative feedback are relatively insensitive to slow changes in internal parameters or external input. However, they may become unstable with increasing feedback. These instabilities fall into three major classes:

1. the appearance of multiple equilibrium states;
2. the creation of autonomous oscillations; and
3. a chaotic behavior with a sensitive dependence on initial conditions and unpredictable variations in state.

It has been mathematically demonstrated that modeling the currently known feedback mechanisms of the dopaminergic system will lead

---

[2] Nancy Pritzker Laboratory of Behavioral Neurochemistry, Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA 94305.

[3] Xerox Palo Alto Research Center, Palo Alto, CA 94304.

to the appearance of these instabilities (King et al. 1981). Herein the authors summarize the relationship between these instabilities and offer predictions about schizophrenic behavior. DA feedback mechanisms involve several time constants: neuronal feedback, occurring rapidly over a period of 1/3 to 2 seconds, activation and deactivation of dopamine synthesis proceeding over periods of 10 to 20 minutes, and long-term up-and-down regulation of dopaminergic receptors occurring over periods of days to weeks. The proposed increased feedback in psychotic individuals will lead to instabilities of behavior on all three time scales. This increased feedback can occur through a variety of mechanisms. For example, an increased release, decreased reuptake, increased synthesis, or increased postsynaptic DA receptor activity will all lead to an increased feedback gain. Likewise, an increased autoreceptor activity, a decreased DA synthesis, or a postsynaptic blockade of dopamine receptors will result in a net decreased feedback. Thus, the former procedures will lead to instability, whereas the latter modifications will rectify that instability. The authors now describe the effect of changing these parameters on the dynamical behavior.

One-third to Two Seconds. Because of the delays in activating and deactivating postsynaptic DA and GABA receptors, a simple stable equilibrium of dopaminergic activity can, by increasing feedback gain, bifurcate into periodic oscillations in dopaminergic firing. These oscillations will have a frequency of the order of the time constant for the delay, that is, 3 Hz to 1/2 Hz. Because the dopaminergic system projects directly to various regions of the limbic system and the striatum, and indirectly projects through the pars reticulata of the substantia nigra to the brainstem, one might expect that psychotic individuals would exhibit this periodic disturbance in activity. Such fluctuating activity has been reported by Ellinwood et al. (1974) in cats treated chronically with amphetamine and by Heath (1954) in subcortical recordings of electrical activity in schizophrenics. Behaviorally this autonomous slow-wave activity might manifest inself, for instance, in the thought disorder, perceptual changes, and eye-tracking disturbances observed in some schizophrenic patients.

Ten to Twenty Minutes. The dopaminergic system is unique among the monoamines in that with both an increase and a decrease in firing, there is an increased activation of dopamine synthesis (Nowycky & Roth 1978). It can be shown that for greater than a fourfold increase in dopamine synthesis at low firing rates, the single homeostatic equilibrium of the dopaminergic system will bifurcate into two stable equilibria. One of these equilibria has a relatively high mean DA output while the other has a lower DA activity. The low dopaminergic state will progressively, with increasing long-loop feedback gain, bifurcate further into oscillations and chaotic activity. This periodic or erratic activity will have a time constant of around 10-20 minutes. In addition, since the dopamine nuclei appear to be loosely coupled, that is, an activation of the one substantia nigra results in a deactivation of the contralateral substantia nigra (Nieoullon et al. 1977), this chaotic activity may decouple the left substantia nigra from the right substantia nigra or a substantia nigra nucleus from a ventral tegmental dopaminergic nucleus. One might, therefore, observe rapid transitions between high and low dopaminergic states as well as spatially decoupled simultaneously activated and deactivated dopaminergic states. This prediction may agree phenomenologically with Bleuler's reports on schizophrenic ambivalence of affect, will, and thought.

Furthermore, the addition of amphetamine, although initially causing a transition from a normal to a chaotic state, could remove a DA nucleus from a chaotic state and place it in a relatively stable high DA activity state. This might explain some of the results reported by van Kammen et al. (1980) on the stabilizing effect of amphetamine given to acutely psychotic individuals.

Days to Weeks. With the bifurcation of DA activity into a low and high DA state, long-term, up-and-down regulation of DA receptor activity could result in oscillations of dopamine function over a period of days to weeks. This behavior can take the form of either bistable oscillations or pulses with rapid transitions from a low to a high DA state. This would be followed by a plateau in DA activity, leading ultimately to a sudden post-plateau drop in DA activity at levels lower than those of the initial DA state. Antleman and Chiodo (1981) have shown that chronic amphetamine, tricyclic antidepressants, and rapid-eye-movement (REM) sleep deprivation may all lead to a subsensitivity of the dopaminergic nigral autoreceptors. Since a decrease in the sensitivity of the autoreceptors causes a net increase in feedback gain, these procedures could lead to a rapidly cycling transition between low to high DA states. Furthermore, if the feedback gain is initially large, the transitions between the low and high dopaminergic states will be chaotic and weakly correlated with transitions from low to high dopaminergic states in other dopaminergic nuclei. Such behavior might be similar to that of an acute schizophreniform psychosis. The schizoaffective psychoses additionally could manifest themselves in oscillations between high and low dopaminergic states that are relatively unsynchronized between neighboring nuclei.

In summary, it is proposed that psychosis results from an excessive DA long-loop feedback. The gain of this feedback circuit can be modified through a variety of mechanisms. Because of the large feedback, a schizophrenic and a nonschizophrenic individual may not differ in the mean values of any parameter monitoring DA activity. However, as a result of the increased instability in DA function, the psychotic individual will show greater spatio-temporal variability in DA activity. On a time scale of seconds, this instability will result in oscillations of neuronal activity that can spread to various subcortical and cortical regions. Over a period of minutes, DA activity will bifurcate into multiple stable states, periodic oscillations, and chaotic activity. On a time course of days to weeks, long-term regulation of DA receptor density can lead to the precipitation of that chaotic or oscillatory behavior. This model is consistent with a variety of genetic and environmental factors leading to a common instability in dopaminergic function.

Retinal Oscillatory Potentials in Schizophrenia: Implications for the Assessment of Dopamine Transmission in Man[1]

Joachim D. Raese, M.D.,[2] Roy J. King, M.D., Ph.D.,[2] Debbie Barnes,[3] Philip A. Berger, M.D.,[2] Jack D. Barchas, M.D.,[2] Michael Marmor, M.D.,[3] and Peggy Hock, Ph.D.[3]

Recently, a new formulation of the dopamine (DA)-hypothesis of schizophrenia has been presented which shows that for certain unstable properties of dopaminergic feedback loops a spatial and/or temporal desynchronization will occur resulting in fragmentation of a dopaminergic nucleus into clusters of cells locked into high and low firing states (King et al. 1981, in press). This restatement of the DA-hypothesis does not predict net changes in DA or its metabolite concentrations.

This hypothesis was tested by examining the properties of the light-evoked oscillations in the retina which can be recorded from the anesthetized cornea. The rationale for this approach is based on several observations: 1) The mammalian contains a substantial concentration of DA (Haggendal & Malmfors 1963) as well as tyrosine hydroxylase (Juvone et al. 1978a, 1978b; Juvone & Neff 1981) in the amacrine cell layer. Retinal tyrosine hydroxylase is rapidly activated by exposure of the eye to light (Juvone et al. 1978a, 1978b). The activation is associated with kinetic changes of the enzyme identical to those occurring in nigrostriatal neurons (Nowycky & Roth 1978). 2) The activation of tyrosine hydroxylase is inhibited by gamma-aminobutyric acid (GABA) (Morgan & Kamp 1980) located together with DA-containing neurons in the amacrine cell layer, suggesting a DA-GABA feedback loop similar to central DA-GABA synaptic connections (Nowycky & Roth 1978). 3) DA-receptors modulate DA-turnover in the retina in a way which is analogous to the brain, i.e., dopamine-blocking drugs such as neuroleptics will increase, and activation of presynaptic receptors by apomorphine will decrease DA-turnover (Wassenaar & Korf 1976). 4) DA-depletion of the retina by reserpine will abolish the oscillatory potentials (OPs) in the rabbit (Hempel 1972-1973) which can be restored by intravitriol injection of the DA-precursor l-DOPA (Gutierrez & Spiguel 1973). The GABA antagonists bicuculline and picrotoxin also abolish the OPs (Wachtmeister 1980), indicating that both intact DA and GABA transmission are necessary for the OPs to be elicited.

In this paper, data are presented which suggest that the OPs are modulated by dopaminergic activity in man. The investigators' approach consisted of: 1) a detailed statistical comparison of waveforms obtained from normal volunteers and drug-free schizophrenic subjects; and 2) stimulation of DA-transmission by amphetamine.

Methods

All patients participating in the study were men (ages 28-58) hospitalized at the Clinical Research Center at the Veterans Administration Medical Center in Palo Alto, California. The patients were managed without use of psychotropic medication for 2 weeks prior to the study. They were given diagnoses of schizophrenia or schizoaffective psychosis using Research Diagnostic Criteria (Spitzer et al. 1978) by three clinicians independently. Patients gave informed consent to the study, which was approved by the Committee on Research on Human Subjects at Stanford University. Patients were rated weekly by two clinicians using the Brief Psychiatric Rating Scale.

Subjects received intraocular drops into the right eye of mydriacyl and neosynephrine to maximally dilate the pupil. After dark adaptation of the eyes for 20 minutes, surface anesthesia was induced by applying novesine drops to the eye, and a contact lens (Burien-Allan) fitted with electrodes was placed on the cornea. A light source (Grass) was placed 25 cm from the eye, its power supply set to maximal intensity (W16), and light stimulation was carried out in 10-second intervals by triggering the lamp and simultaneously a sweep of 100 msec duration on a storage oscilloscope (Tektronix). Oscillatory potentials were recorded using a frequency filter attenuating frequencies below 100 Hz. Traces stored on the oscilloscope screen were photographed using a Polaroid camera.

The negative and positive deflections constituting the retinal light-evoked response were measured as shown in Fig 1-A and will be referred to as Relative Amplitudes (RA). Positive RA were assigned the labels 0[1], 0[2], and 0[3] in order of their latencies from the stimulus. Similarly, negative RA were termed N[1], N[2], and N[3] such that the alternating positive and negative RA of the waveform are described by the sequence 0[1] − N[1] − 0[2] − N[2] − 0[3] − N[4] (Figure 1-A). Latencies were measured as shown in Fig 1-B by determining the distance from the first negativity to the first peak 0[1] and assigned the label Δ0[1]. The distance representing the time elapsed from 0[1] to the trough N[1] was termed ΔN[1], etc. ΔO[1] through ΔN[3] will be referred to as Relative Latencies (RL).

All values of Relative Amplitudes were scaled by calculating their natural log. These natural logs were used to calculate the means, standard deviations, and variance of 5 to 11 measurements of each RA in each subject. The grand pooled variance for the RAs 0[1] through N[3] was determined for eight normal subjects and nine schizophrenic patients utilizing between 55 and 70 measurements for each RA for each of the two groups

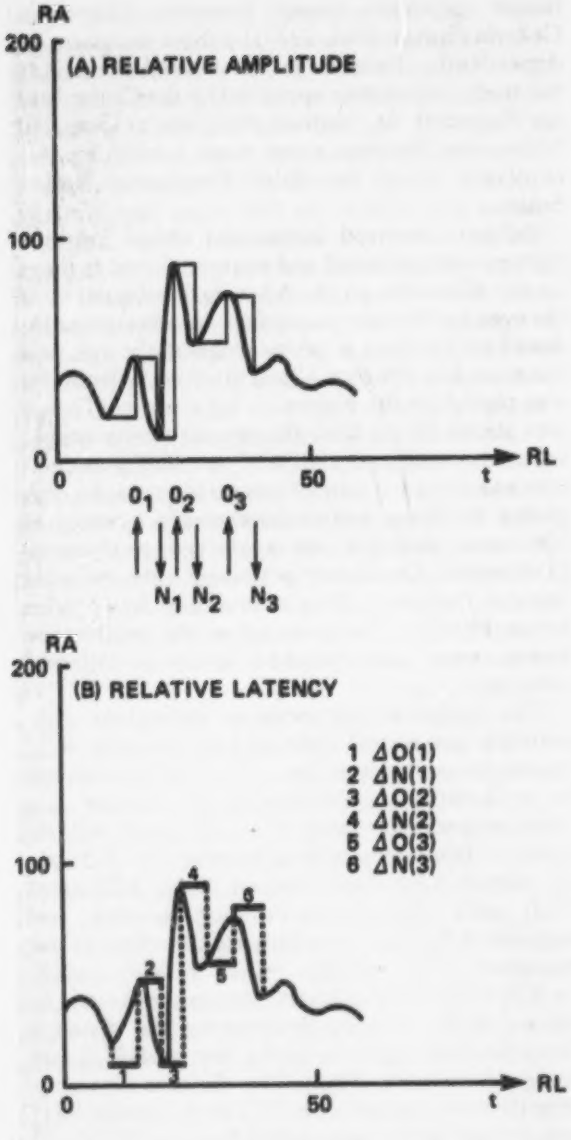

FIGURE 1. Determination of Values for the Major OP-Waveforms. We define the sequence 0[1], N[1], 0[2], . . . and A) determine the length RA = Relative Amplitude = $PA_i - PA_{i-1}$. B) Time (t) elapsed from stimulus (t = 0) is measured and the sequential periods labeled 1, 2, . . . 6 are assigned the labels Δ0[1], ΔN[1], . . .ΔN[3] = Relative Latencies.

Relative latencies were evaluated similarly except that unscaled values were used. Variances were compared by *F*-statistics, means by two-tailed *t*-test.

Results

Increased Variability of OPs in Schizophrenic Subject

Light stimulation of the dark adapted retina produces oscillatory waveforms characterized by increasing amplitude and stabilization of the oscillations in response to consecutive light flashes. Fig 2, A-C, illustrates that the OPs in three normal volunteers have stabilized after three light flashes.

Oscillatory potentials recorded from three schizophrenic patients are shown in Fig 2, D-F. Visual inspection reveals a lack of synchronization of the waveform.

In order to quantify this observation, the Relative Amplitudes and Latencies were determined as described in the Methods section. The Table shows the variances of RA and RL, respectively, of 11 normal and 11 schizophrenic subjects. Compared to normal subjects, schizophrenics had significantly greater variance of RA N[1] and N[3] while N[2] approached significance. The positive deflections 0[3] had similar variance in both groups. 0[1] and 0[2] had significantly higher variance in the control group. It should be noted that a major portion of this variance was contributed by one control subject who had extrememly high variance in this parameter. Interestingly, the subject has carried the diagnosis of dyslexia since childhood. This observation deserves further investigation.

The Table shows significantly higher variance in schizophrenia of RL ΔN[1] through Δ0[3], which corresponds to the time span encompassing the major OPs (*see* Figure 1, A and B), indicating that the time evolution of the central part of the evoked waveform is quite variable in schizophrenic subjects.

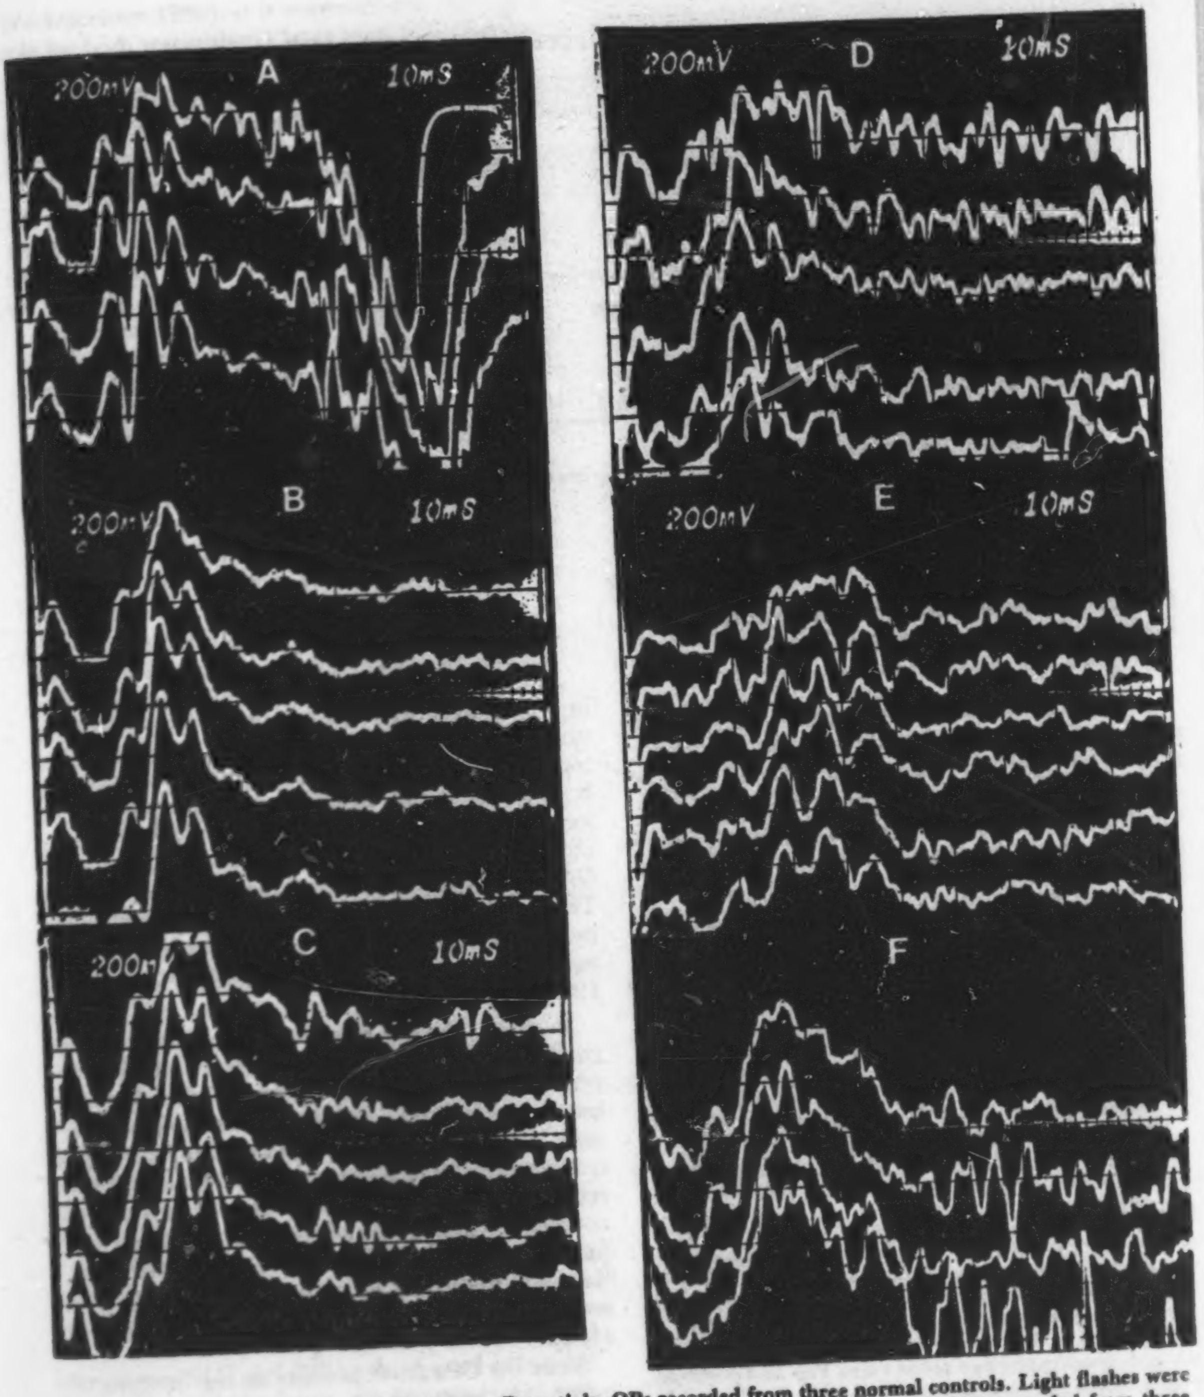

FIGURE 2. Oscilloscope Traces of Oscillatory Potentials. OPs recorded from three normal controls. Light flashes were given at a rate of 1 per 10 seconds. Sequence is from top to bottom of each panel (A - C). OPs recorded from three schizophrenic patients (D - F).

Table

Variance of Relative Amplitudes and Latencies of OPs

			Relative Amplitudes			
RA	0[1]	N[1]	0[2]	N[2]	0[3]	N[3]
Schizophrenia σ_p^2	.050	.150	.030	.190	.116	.073
Controls σ_p^2	.076	.106	.071	.142	.129	.043
p<	.026	.005*	.001	.08*	N.S.	.006*
			Relative Latencies			
RL	Δ0[1]	ΔN[1]	ΔN[2]	ΔN[2]	Δ0[3]	ΔN[3]
Schizophrenia σ_p^2	.012	.003	.008	.012	.003	.011
Controls σ_p^2	.012	.002	.003	.003	.002	.019
p<	N.S.	.05*	.001*	.001*	.05*	.005

*Schizophrenia > Controls
All others, Controls > Schizophrenia
Eleven controls and eleven schizophrenic subjects were studied and their OPs analyzed as described in the text. The variances (σ_p^2) of RA and RL values are shown. Significance was calculatec using the *F*-distribution.

Effect of Acute *D*-Amphetamine on the Relative Amplitude of the OPs

Baseline recordings were obtained from five subjects. One hour before their second recording they were given a single oral dose of 15 mg *d*-amphetamine. Amphetamine increased the mean relative amplitude (RA) of the oscillations (Fig 3) with the largest effects on 0[1], N[1], and N[2].

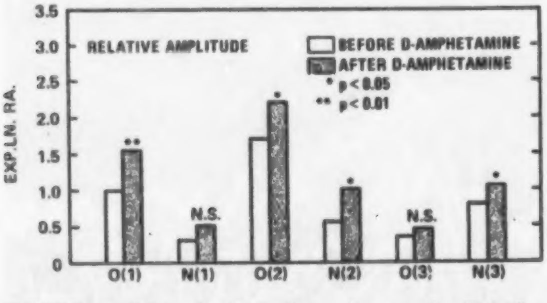

FIGURE 3. Effect of *d*-Amphetamine on the Relative Amplitude of Oscillatory Potentials. Two recordings were obtained from each subject. Subjects were given 15 mg of *d*-amphetamine orally 1 hour prior to their second recording session. The means of the natural log transforms of the RA obtained in the two sessions were calculated for each RA and compared by two-tailed *t*-test. Pre- and postdrug values of RA are plotted after exponentiation (exp. LN .RA).

Discussion

Animal studies suggest that the OPs originate in deeper layers of the retina, the earlier potentials originating in different layers than the later ones, indicating a radial flow of current (Wachtmeister & Dowling 1978). In addition to this particular anatomical organization, the individual OPs are characterized by differential sensitivity to the GABA antagonists bicuculline and picrotoxin. The latter observation is consistent with the hypothesis that different transmitters may be modulating earlier and later OPs (Wachtmeister 1980).

In this study, the OPs were recorded from the cornea, i.e., at a great distance from where they originate. The recording represents, therefore, an integration of the activity of entire cell populations which must be firing synchronously in sequence in order to generate the oscillatory evoked response. This behavior is consistent with that of coupled oscillators time-locked to a stimulus. It has been suggested that the OPs reflect the radial flow of current through feedback loops connecting retinal layers of different depths (Wachtmeister 1980).

Since the OPs are dependent on the integrity of both DA and GABA transmission (Hempel 1972-1973; Gutierrez & Spiguel 1973;

Wachtmeister 1980), it is reasonable to assume a role for both transmitters in at least some aspects of their regulation.

Several findings are presented suggesting a modulatory role for dopamine in the generation of OPs in man:

1) *d-amphetamine, a compound known to enhance DA-transmission, significantly increased the amplitude of the OPs.* To the best of our knowledge, this is the first report of a direct effect of DA-transmission on the OPs of man.

There are only two brief reports on pharmacological manipulation of DA on the raw electroretinogram (ERG). A single oral dose of thioridazine (50 mg) caused a prolongation of the a-wave latency and b-wave evolution time, as well as a diminution of b-wave amplitude in normal volunteers (Filip & Balik 1978). The same group reported the lack of an effect of 500 mg L-DOPA on the same ERG parameters (Balik & Filip 1978). In neither study, however, were the OPs recorded.

Since the OPs ride on the ascending slope of the b-wave, it is conceivable that amphetamine could influence the OPs through b-wave changes. Examination of b-waves obtained pre- and postdrug treatment, revealed no significant increase or decrease of the b-wave (data not shown). This finding is in keeping with the observations that b-wave and OPs originate in different layers of the retina and that compounds such as GABA and glutamate, which profoundly affect the OPs, have no effect on the b-wave (Wachtmeister 1980).

2) *Schizophrenic patients have higher variance of OPs than controls.* The variance of the RAs of the first six negative and positive deflections of the OPs and the Relative Latencies in 11 control and 11 schizophrenic subjects were analyzed (Table). The negative RAs N[1], N[2], and N[3] had greater variance in the schizophrenic group. This "selectivity" militates against the argument that a "nonspecific" increase in noise could account for the desynchronized appearance of the OPs (Figure 2). The variance of the RL in the schizophrenic group is significantly increased in $\Delta 0[2]$ through $\Delta 0[3]$ which together constitute the major part of the entire waveform.

It should be pointed out that the increased variances of 0[1] and 0[2] in the control group are due to one control subject who had extremely high variances in these parameters. The subject had no psychiatric history but suffered from developmental dyslexia. Further studies will be necessary to decide whether there is a causal relationship of ERG parameters and that diagnosis.

Ranking the 11 patients according to their OP variance revealed that the major contribution of the pooled group variance was contributed by five patients, all of whom suffered from auditory hallucinations.

Although our total group size is small, this finding suggests the existence of subgroups of schizophrenic patients who may be differentiated by using the OPs record as criterion. This preliminary finding would suggest that desynchronized OPs may be associated with productive symptoms such as auditory hallucinations.

A Convergence of Findings in the Psychophysiology of Schizophrenia[1]

Walton T. Roth, M.D.,[2] and Jared R. Tinklenberg, M.D.[2]

The history of the psychophysiology of schizophrenia has been similar to the history of other research approaches to this disease. Instead of steady progress over time, there have been sporadic reports of cardiovascular, electrodermal, EEG spectral, and, most recently, event-related potential (ERP) abnormalities that have proved minor, secondary, or unreplicable. Furthermore, there has been no theory to coordinate the diverse physiological measurements and give direction to experimental programs, except for the very general concept of activation or arousal, which is often applied in a post hoc fashion to explain whatever physiological differences are observed. Activation is probably more relevant to the understanding of anxiety states than to psychosis, though it would not be surprising to find high tonic levels of activation in patients whose psychosis has made them fearful.

Recently, a possible convergence of findings has become apparent that is consistent and unexpected. Skin conductance response (SCR) nonresponding and ERP P300 reduction have been observed in schizophrenic patients repeatedly in the last 10 years by groups of researchers who were quite unaware of each other's techniques, literature, and theories. That unawareness, though unfortunate in many ways, lends an element of independent verification to these findings, if a theoretical and empirical bridge can be built to show that the two phenomena have the same psychobiological basis.

SCR is a transient decrease of skin resistance to novel or otherwise salient stimuli, usually measured on the palm where it has a latency of 2 or 3 seconds. The essential facts about SCR and psychosis are these:

1. SCR nonresponding is defined as responding once or not at all in a standard habituation paradigm with 75 dB sound pressure level, 1-second tones, and inter-stimulus interval (ISIs) from 25 to 45 seconds. According to this definition, 50 percent of schizophrenics are nonresponders, while only 15 percent of controls are nonresponders. Retarded depressives also have higher incidence of nonresponding than controls.
2. The ratio of evoked SCR/spontaneous SCR is much less for schizophrenics than for controls. This excludes simple arousal explanations.
3. Nonresponding schizophrenics become responders if the tone intensity in the habituation paradigm is increased or if a response is required.
4. Nonresponding schizophrenics are characterized clinically by emotional withdrawal, conceptual disorganization, and depressed mood.
5. There is some evidence that nonresponding is a trait: it has a higher incidence in preschizophrenics, and nonresponding schizophrenics continue to be nonresponders after clinical remission.

These assertions are based on investigations reviewed by Venables (1977) and Öhman (1981), who provide exhaustive lists of relevant references.

The phenomenon of nonresponding is extremely well-documented: at least five independent research groups in England, the USA, the Federal Republic of Germany,and Norway have observed it. Nonresponding is seen in both acute and chronic, medicated, and unmedicated patients, though not many first-episode, unmedicated schizophrenics have been tested. Although 15 percent of controls are nonresponders by standard criteria, these subjects may be nonresponders of a different kind than the majority of schizophrenics. Certain subjects fail to show SCRs to any stimuli, presumably because of innate differences that have no psychological meaning. More stringent criteria—for example, only considering subjects to be nonresponders if they evince "spontaneous" SCRs or SCRs to intense stimuli but fail to give SCRs in the standard habituation paradigm—may result in fewer false positives, i.e., nonresponding controls.

P300 by its designation is a positive ERP with a latency of about 300 msec. It has an amplitude on the order of 10 μV at a parietal midline location referenced to the ears or mastoids. Its latency and amplitude are not fixed, but vary widely according to the nature of the stimuli and the way the subject processes them. Table 1 lists 15 investigations of P300 in clinical groups. The investigations were carried out in eight independent laboratories in the USA, Canada, and the Federal Republic of Germany. P300 reduction is present in both unmedicated and medicated schizophrenics; however, as for SCR, few first-episode, unmedicated schizophrenics have been tested in P300 paradigms.

The most common paradigm for eliciting P300 has been designated the "oddball" paradigm in Table 1, following a usage in the ERP literature. The paradigm has the following properties: Two or more easily discriminable types of stimuli, often tones of two pitches, are presented repeatedly at a fixed ISI, usually between 1 and 3 seconds. One type of stimulus is less frequent than the other(s), and is usually made a target for a counting or reaction time (RT) task. These conditions are conducive to the generation of P300s to the infrequent stimuli, at least in normal subjects. Schizophrenics were found to have reduced P300s compared to controls in all paradigms except the two listed as 7C and 15, both of which deviated significantly from the oddball paradigm.

P300 reduction does not appear to be simply a reflection of poorer task performance on the part of schizophrenics. In Studies 6A, 10, and 13, differences remained even when performances were matched between groups. In Study 1, in which subjects were told to *ignore* the stimuli, the schizophrenic P300 reduction could be regarded as better performance since smaller P300s indicate that less attention was paid to the stimuli. However, the relation between ERPs and performance is a complex one, and the consequences of the reduced task involvement often found in psychotic experimental subjects are often subtle (for a review, see Roth, in press-a).

Are SCR nonresponding and P300 reduction in schizophrenics due to the same psychological or biological process? In the past 10 years a great deal has been learned about experimental

variables that control P300 amplitude and latency (for reviews, *see* Pritchard 1981, and Donchin 1981). When the findings are put in perspective, astonishingly close empirical and theoretical parallels can be drawn between P300 and SCR. The categories under which these similarities can be enumerated are listed in Table 2. Both P300 and SCR can be elicited by stimuli of diverse types, both are enhanced by various kinds of stimulus surprise, task relevance, and salience, and both show habituation. Neuronal and probabilistic models developed by Sokolov and others apply equally well to both responses. Cognitive and computer models of stimulus evaluation and context updating developed for P300 by Donchin and his students are being applied to SCR. A detailed documentation of these parallels can be found by Roth (in press-b).

In a psychological sense, both SCR nonresponding and P300 reduction imply an inability to mobilize extra stimulus processing resources when the novelty or other features of the stimuli warn that additional resources may be required momentarily. These extra resources may actually turn out to be unnecessary, in that RT or counting tasks of a simple nature can be performed adequately with the available resources even when the stimulus comes as a surprise. The differences between psychotics and controls in mobilizing these resources may be apparent only at intermediate levels of stimulus novelty or task demand. When stimuli are expected and uninteresting, neither group responds; when stimuli are very novel, task-relevant, or intense, both groups may respond equally.

In a biological sense, SCR nonresponsivity and P300 reduction imply a failure of components of the orienting reflex. This innate basic mechanism for reacting to potentially dangerous stimuli in the environment is found in both vertebrates and invertebrates (e.g., Kandel 1981).

Our unitary interpretation of SCR and P300 could be challenged on the basis of the results of Cohen et al. (1981). Their study is up to now the only one to report SCR and ERP measures in the same patients, although from different paradigms. As usual, about half of the schizophrenics were SCR nonresponders in a habituation paradigm, but both SCR responders and nonresponders had reduced P300s in an oddball paradigm. Either their P300 paradigm was more sensitive than their SCR paradigm to a general schizophrenic deficit that differs quantitatively among schizophrenics, or their SCR paradigm differentiated subgroups of schizophrenics that differ qualitatively from each other. Although SCR and P300 are generally under the control of the same independent variables, it is possible that they reflect distinct and dissociable information processing mechanisms (*see* Roth, in press–b).

Since it has been suggested that there are at least two biologically distinct types of schizophrenics, one suffering from dopaminergic hyperactivity and the other from enlarged cerebral ventricles (Crow 1982), it is tempting to try to assign SCR nonresponders to one of these types. However, definite assignment of SCR or P300 abnormalities to specific subtypes of mental disease must await systematic investigations in which patients are studied from multiple perspectives simultaneously. Nonresponsivity should be assessed in various physiological systems from the brain to the periphery, and these data should be compared with biochemical, radiological, psychological, linguistic, and clinical-historical data. Converging findings may help us discover groups of patients with diseases of distinct etiologies and prognoses.

Pituitary-Adrenal Assessment in Identifying Subtypes of Depression

Walter Armin Brown, M.D.,[1] and C. Brandon Qualls, M.D.[2]

About 50 percent of patients with primary major depressive disorder show pituitary-adrenal disinhibition while they are depressed but not after recovery. This endocrine phenomenon provides a model for examining the value of a biological marker in subtyping depressive illness.

The dexamethasone suppression test (DST), because of its procedural simplicity, lack of risk, minimal discomfort to the patient, relative ease with which normal and abnormal responses are differentiated, and demonstrated clinical correlates has been the method most widely applied for assessing pituitary-adrenal activity in studies of psychiatric patients. Recent studies using the DST in depressed patients have examined the clinical correlates of normal and disinhibited pituitary-adrenal activity. With respect to existing diagnostic categories, Brown and Shuey (1980) and others (Schlesser et al. 1980) have found that nonsuppression after dexamethasone occurs almost exclusively in patients with primary major depressive disorder; very few patients with secondary depression (those with a preceding psychiatric diagnosis other than affective) show nonsuppression. Carroll and his associates (Carroll et al. 1981) have reported that nonsuppression occurs exclusively in patients with endogenous depression or melancholia; patients with nonendogenous depression showing normal suppression. Yet whether one examines patients who meet criteria for melancholia, primary depression, or endogenous depression, one finding has been consistent from study to study: Patients in each of these diagnostic categories are heterogenous in their pituitary-adrenal activity. Depending on the DST protocol, 30 to 65 percent are nonsuppressors and the remainder suppressors. This heterogeneity has focused the authors' attention on dimensions of depressive illness other than diagnosis that might correlate with pituitary-adrenal activity.

Although in a few studies (Davis et al. 1981) nonsuppressors have been observed, on the basis of rating scale scores, to have a more severe depression than suppressors, this is not a consistent finding (Brown & Qualls 1981). A few patients who have been nonsuppressors during one major depressive episode have been studied during subsequent periods of depression. Nonsuppression has occurred in these patients only in the context of severe depressive symptomatology, not with minor or transient depression (Brown & Qualls, unpublished observations). Thus there may be a severity threshold for nonsuppression.

However, since many suppressors have, by any criteria, a severe illness, the differences in pituitary-adrenal activity among depressed patients are not likely to be accounted for by differences in severity of illness.

Nor do suppressors and nonsuppressors differ consistently in the occurrence or intensity of suicidal ideation, agitation, anorexia, sleep disturbance, or other specific depressive symptoms. Yet one symptom dimension in depressed patients—cognitive impairment—does appear to consistently correlate with pituitary-adrenal activity. Nonsuppressors have more difficulty than suppressors in completing self-rating scales (Brown & Shuey 1980), have longer reaction times (Brown & Qualls 1981), are rated as having greater thinking disturbance (Reus 1982), and make more errors of commission on a recognition task (Reus, unpublished observations). Further, a significant positive correlation has been observed between urinary cortisol and number of errors on the Halstead Categories Test (Rubinow, unpublished observations). In summary, the studies to date have consistently shown that depressed patients with pituitary-adrenal disinhibition have a greater degree of cognitive impairment than those with normal pituitary-adrenal regulation.

Nonsuppressors have been found to differ from suppressors on three dimensions of illness course: they are older at both the index episode and their first depressive episode (this age difference appears to be sex related; it occurs most clearly in depressed women); irrespective of treatment, nonsuppressors seem to undergo greater improvement during hospitalization (Brown & Qualls 1981; Greden et al. 1980); and, retrospective studies show that nonsuppressors have more episodes of depression (Brown & Qualls 1981; Schlesser et al. 1980).

A few studies, all of which must be considered preliminary, suggest that nonsuppressors and suppressors differ in their response to specific treatment. Whereas nonsuppressors appear to respond well to desipramine and imipramine (Brown & Qualls 1981; Greden et al. 1981), they show a poor response to clomipramine (Brown et al. 1980) and mianserin (Cobbin et al. 1981). Suppressors, on the other hand, seem to respond equally well to these antidepressants. Clearly, more data are needed to definitively answer the question of whether suppressors and nonsuppressors respond preferentially to different antidepressants. The little data available so far lend themselves to the interpretation that nonsuppressors respond better to drugs having their predominant effects on noradrenergic rather than serotonergic systems. This preferential drug response would be consistent with the known serotonergic excitatory and noradrenergic inhibitory input to pituitary-adrenal regulation.

Suppressors and nonsuppressors appear to differ in their response to electroconvulsive therapy (ECT). The authors have found that of 13 suppressors and 12 nonsuppressors treated with ECT clinical improvement occurred in all of the suppressors but in only six (50%) of the nonsuppressors. Six nonsuppressors did not respond to ECT according to both rating scale criteria and their clinician's impressions. These observations are consistent with those of Papakostas et al. (1981) who, although not directly addressing the predictability of the DST for ECT response, reported that 5 of 14 nonsuppressors treated with ECT did not improve, a higher than usual rate of nonresponse.

Suppressors and nonsuppressors differ in their responses to methylphenidate and sleep deprivation, treatments which induce in some patients a transient relief of depressive symptoms. Significantly more suppressors than nonsuppressors show an antidepressant response to methylphenidate (Sternbach et al. 1981), but more nonsuppressors than suppressors respond to sleep deprivation (Nasrallah & Coryell 1982).

The apparent differences between suppressors and nonsuppressors in course of illness and response to specific treatments suggest that the depressive illnesses associated with normal and abnormal pituitary-adrenal regulation differ in their pathophysiology. Two other bits of data support this concept. Schlesser and his associates (1980) reported that nonsuppressors are more likely to have a family history of depression than suppressors; and, the authors have found (1982) that people are consistently suppressors or nonsuppressors over multiple depressive episodes. These observations suggest that the depression associated with pituitary-adrenal disinhibition may, more so than other depressive illnesses, have a genetic component and, consistent with this, there may be stable individual differences in the propensity to develop pituitary-adrenal disinhibition with depression. Thus pituitary-adrenal assessment may identify a subtype of depression having a distinct pathophysiology with characteristic clinical and treatment response features.

Diagnostic categories based on symptomatic phenomenologic criteria rarely identify illnesses which are homogeneous with respect to etiology, pathophysiology, or treatment requirements. Many illnesses that differ little if at all symptomatically have differing underlying pathophysiologies that are critical in determining effective treatment and prognosis. Pneumonia, hypertension, and probably depression as well, are among them. On the other hand, as with vitamin deficiencies, porphyria, and syphilis, a single pathophysiologic process which must be identified for effective treatment, can have differing symptomatic presentations. Pituitary-adrenal disinhibition may be associated with a psychiatric illness having a number of symptomatic presentations, depression perhaps the most common. Such an illness might respond, however, to one or more specific treatments. One study has shown that among patients with mixed psychiatric diagnoses including catatonia, schizoaffective disorder depressed, and paranoid schizophrenia, nonsuppressors regardless of "diagnosis" but not suppressors, respond to thymoleptic treatments—lithium, ECT, and secondary amine tricyclics (Carman et al. 1980).

Among depressed patients pituitary-adrenal disinhibition is associated with cognitive impairment, a tendency to recurrence, and an emerging profile of response to specific treatments. This neuroendocrine dysfunction and other neuroendocrine and neurochemical markers may help reorient our thinking about the dimensions of psychiatric illness relevant to "diagnosis" and provide a stepping stone to a classification of depression more closely tied to pathophysiology and treatment than current phenomenologic approaches.

Benzodiazepine Abuse: What Are the Data?

Chair: Charles P. O'Brien, M.D., Ph.D.
University of Pennsylvania
VA Medical Center
Philadelphia, Pennsylvania

Subjective Effects of Benzodiazepines and Methaqualone in Recreational Sedative Users

Jonathan O. Cole, M.D.,[1] Maressa Hecht Orzack, Ph.D.,[1] Francine M. Benes, M.D., Ph.D.,[1] Barbara J. Beake, A.B.,[1] Michael P. Bird, A.B.,[1] Yoram Bar Tel, M.A.,[1] and Martin Ionescu-Pioggia, A.B.[1]

Sedative drugs, including methaqualone and various barbiturates, are generally agreed to have abuse potential and are used recreationally as "street" drugs. Some individuals become physically and psychologically dependent on these agents. Recreational use of benzodiazepines is less well documented, though some reports exist, and physical dependence is believed to be relatively uncommon. Nevertheless, a number of cases of physical dependence have been documented in the world literature.

If one assumes that the relative abuse liabilities of various benzodiazepines are unclear, one feasible approach to documenting their abuse liabilities would be to compare them, first, to each other and, second, to a sedative drug of known abuse potential such as methaqualone. Our group is currently engaged in a program of studies which is working toward this objective. The present paper should be viewed as a progress report on work completed to date. Two studies, one comparing methaqualone in single doses of 200 mg and 400 mg with placebo and a second comparing 20 mg of prazepam with 10 mg of diazepam and placebo, have been completed. Studies directly comparing a higher dose of diazepam (20 mg) with higher doses of prazepam (40 mg) and with methaqualone are now in progress.

Methaqualone had been selected as a "standard" abuse-liable sedative because of its popularity with recreational sedative users in the Boston area. It is a chemically synthesized molecule which belongs to a group of compounds called the oxoquinazolines. As such, it is structurally similar to piperidone and barbiturate hypnotic drugs (Brown & Goenechea 1974). Methaqualone is absorbed rapidly after oral administration (Meyer & Boggan 1977) and, in man, average peak plasma levels occur at 2 hours after administration (Morris et al. 1972). Unbound plasma methaqualone is free to diffuse passively into the cerebrospinal fluid compartment in proportion to its concentration (Christensen & Holfort 1975). The primary route of metabolism of the drug is through the hepatic microsomal mixed oxidase enzymes (Prabhu et al. 1964). SKF 525-A, a compound which inhibits the liver metabolism of methaqualone, enhances its distribution into various subcellular compartments within the brain, including cytoplasm, myelin, and, to a much lesser degree, synaptosomes, mitochondria, and microsomes (Kuhn & Shah 1978). Within 8 hours of oral administration, 80-90 percent of the drug present in plasma has been cleared (Morris et al. 1972), the principal route or excretion for methaqualone and its metabolites being through the urine. In human subjects, its rate of elimination is quite variable, and the estimated half-life of methaqualone in urine can be as long as 74 hours (Heck et al. 1978).

---

[1] Psychopharmacology Program, McLean Hospital-Harvard Medical School, Belmont, MA 02178.

Methaqualone is a short-acting anesthetic and muscle relaxant which in man produces slow wave changes in the electroencephalogram (EEG) similar to those observed with barbiturates (Saxena et al. 1977). The ability of methaqualone to reduce seizure susceptibility in mice (Boggan et al. 1977) appears to be associated with enhancement of transmission at GABA-nergic synapses in the central nervous system (Naik et al. 1978). Although methaqualone is a potent inhibitor of specific ^{3}H-diazepam binding to rat brain synaptosomal membranes (Muller et al. 1978), its central depressant effects do not appear to be mediated through a direct action of GABA receptors (Naik et al. 1978). As a lipophilic substance which has been demonstrated in various brain compartments, the range of possibilities to account for its various actions is very broad and its interaction with GABA-nergic neurons may be only one of many possible mechanisms of action in the central nervous system.

In addition to its clinically useful physiological effects, methaqualone has euphoriant, relaxant, and anxiolytic properties which have been associated with its recent widespread nonmedical use (Gerald & Schwirian 1973). Individuals who take methaqualone consistently report its preferred use in social settings (Gerald & Schwirian 1973; Kochansky et al. 1975), and its apparent aphrodisiac properties appear to be among its most desirable effects (Gerald & Schwirian 1973). Studies of methaqualone effects in monkeys have demonstrated an increase of "affiliative activities" including grooming, huddling, and sitting together, although curiously, sexual functions while under the influence of the drugs were primarily autoerotic (Claus et al. 1980).

The accumulated experience with nonmedical use of methaqualone has revealed that a variety of complications can arise. Interference with memory recall and stimulus discriminability (Rundell et al. 1975), tolerance (Faulkner et al. 1979), physical dependence (Singh et al. 1980), abstinence syndromes with potentially life-threatening seizures (Swartzburg et al. 1973), and peripheral neuropathy (Mark & Sloggem 1976) are among the more serious complications of long-term methaqualone abuse. In addition, methaqualone-diphenhydramine (Mandrax®), a commercially produced combination drug, has also been associated with dose-related psychotic reactions, intoxication-related suicide attempts, and violent episodes (Tennant 1973).

Despite its potential complications, methaqualone is a sedative hypnotic with considerable abuse potential which appears to derive from its recreationally desirable effects. As such, it represents a useful investigative tool to explore the effects of such agents on individuals and their social interactions under controlled laboratory conditions. Such a controlled laboratory setting employing standardized assessment batteries, once established, could later be applied to the study of other sedative hypnotic drugs to determine their respective abuse liability relative to methaqualone as a reference standard. Methaqualone has been evaluated for subjective and physiological effects by Jasinski et al. (1977) and found generally comparable to pentobarbital in its subjective effects.

The prazepam-diazepam comparison was undertaken on the presumption that diazepam's relatively rapid absorption, which gives peak blood levels 30-90 minutes after oral ingestion (Bliding 1974), might make it more subjectively reinforcing than prazepam which is converted into desmethyldiazepam in the body and gives peak plasma levels of this compound only at about 6 hours (Chang et al. 1978). In our clinical experience patients often feel more rapid relief from anxiety on diazepam than on other benzodiazepines. The doses were selected as representing high standard clinical dosage units (Woody et al. 1975). Higher dosages are often selected for recreational purposes, but lower dosages were chosen to work out a useful methodology before higher levels were studied.

The designs for both studies were essentially identical. Subjects were recruited by notices posted in various local colleges. Most were students from socio-economically upper middle or upper class families who were college educated. All participants were casual users of sedative-hypnotics, such as barbiturates, methaqualone, and benzodiazepines, and had used one or more of these drugs at least six times in doses above the usual prescribed levels. Subjects were required to complete the Minnesota Multiphasic Personality Inventory (MMPI) (Dahlstrom et al. 1972) and undergo a clinical interview. The latter was conducted by a clinical psychologist who determined previous drug usage, probed for areas of personality dysfunction and adverse reactions to stress, and reviewed the psychiatric history of the subject and his family of origin. Results from both the MMPI and the clinical interview were used as criteria on which to judge the subjects' suitability for participation. The mean MMPI profile of male and female subjects showed elevations of scales 4 (Pd — psychopathic deviate) and 9 (Ma — mania), but these were below a T-score of 70. This pattern is characteristic of a hypomanic and sociopathic personality style that is generally within the range of normal behavior (Dahlstrom et al. 1972). In addition, subjects had a normal physical examination, no history of drug dependence including alcohol, and had no unusual side effects during their previous drug experiences.

Separate groups of 24 subjects, 12 male and 12 female, were recruited for the methaqualone and the diazepam-prazepam studies. Four subgroups of six subjects each, two male subgroups and two female subgroups, were created.

Measures

The major dependent measure for the present report was List 116 of the Addiction Research Center Inventory (ARCI), a 102-item inventory which characterizes the subjective effects of a drug compared with those of other well-known drugs of abuse (Haertzen 1974). This version contains seven standard scales in addition to an 11-item Amphetamine scale developed by Martin et al. (1971) plus Euphoria and Sedation scales established by Jasinski et al. (1977). The utility of these scales in investigating the subjective effects of various substances is well documented (Martin et al. 1971; Jasinski 1977; Jasinski et al. 1977).

Although the ARCI was originally a true/false questionnaire, we devised two variants for use in these studies. For the methaqualone study, a 7-point version was used; subjects were asked to rate themselves on intensity from 0 to 6. For the prazepam study, a 10-point version was used; subjects were asked to rate themselves on each item from −5 to +5. The same scales were used in both studies, but the actual numerical scores obtained on the scales are not strictly comparable across studies. Different versions of the Profile of Mood States (POMS) (McNair et al. 1971) were used in the two studies; neither version seemed as sensitive to drug-placebo differences as the ARCI. The POMS results will not be presented at this time.

Testing Procedures

Subjects were run in groups of six, with each group coming in for three 5-hour sessions, 1 week apart. Each subject in fact received all three treatments (20 mg of prazepam, 10 mg of diazepam and placebo, or 400 mg and 200 mg of methaqualone and placebo) in random order and double-blind. Thus, each subject served as his or her own control for the experiment. Randomization of treatments ensured that only two subjects in each group were receiving the same drug during each session. Subjects themselves were not aware that they would receive a different treatment at each session, and only knew the possible treatments they *could* receive.

Subjects were instructed to abstain from drug usage for 72 hours and alcohol for 12 hours prior to each session; they were asked to give a urine sample at the beginning of the session to be screened for illicit drug usage that might interfere with the validity of their ratings. No illicit use was detected. Initial physiological measures including pulse, temperature, and blood pressure were obtained. Pulse determinations were repeated hourly, while blood pressures were obtained only at the beginning and the end of each session.

The POMS and ARCI self-rating questionnaires were administered at the outset (predrug) and then hourly for 4 (methaqualone) or 5 (prazepam) hours following drug ingestion. Subjects were also asked to guess which drug they thought they and the other subjects received, what rate they would pay for what they had received, and how high they felt during the session.

Groups were run in a living-room-like atmosphere in which subjects were free to play games, talk, read, listen to music, and eat, starting 1 hour after drug ingestion during the times when they were not filling out ratings. Each rating took about 25 minutes, leaving the subjects a substantial amount of free time.

Table 1

Covariance F-Ratios of ARCI Scores: Methaqualone Study

Scale	Drug	Time	Sex	Drug-Time	Time-Sex	Drug-Sex
Amphetamine	16.90**	37.25**	4.72*	7.27**	1.98	0.34
Drunkenness	31.66**	26.42**	5.83*	12.83**	1.85	1.35
Excitement	5.32**	35.45**	7.67**	7.37**	0.34	0.02

Data Analysis

The F values and corresponding probabilities for main drug effects, time effects, sex effects, and interaction among these variables were obtained by an analysis of covariance (grouped by sex) which adjusted for variations in the subjects' predrug ratings. The baseline scores (predrug) depicted in the figures represent raw means for each scale, while postdrug scale scores have been covaried. No significant differences between the three treatment groups were observed on baseline ratings in either study. Results of this analysis for the ARCI are presented in Table 1 for the methaqualone study and in Table 2 for the prazepam study. Where main drug effects, drug-by-time interactions, or trends were observed, an analysis of variance of adjusted mean scores was performed for each separate time point on that measure. Differences between drug conditions at these time points were analyzed using a Neuman-Keuls multiple comparison statistic.

Results

Within both studies in the major analysis of covariance, main drug effects and drug-by-time interactions significant at the $p < .05$ level were taken as clear evidence of drug treatment differences. Significant main drug effects occurred when, by inspection, level differences between treatments, usually drug and placebo, were evident throughout the entire study period, while drug-by-time interactions were statistically significant when drug-placebo differences were marked at one or two time periods, usually 1 and/or 2 hours after drug ingestion and then dwindled as the study period continued.

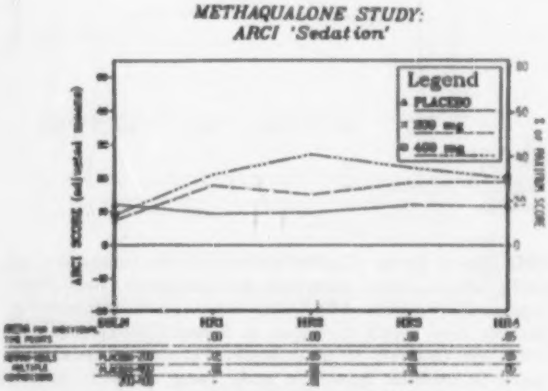

FIGURE 1. Drug vs. time curves for the comparison of orally administered methaqualone. Each point represents the mean ARCI scale score of each treatment at the five time levels (baseline to 4 hours post), adjusted from the analysis of covariance. Percent of maximum score is derived from the scale range (0-66): (mean score/scale range) x 100. Below the plot are displayed the results of the post hoc drug by time ANCOVA at each time point, and the Neuman-Keuls contrasts indicating drug-placebo/drug-drug differences.

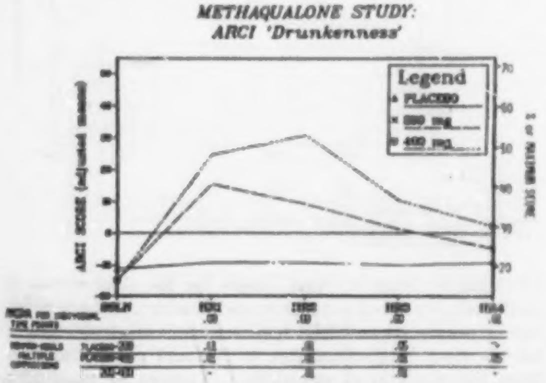

FIGURE 2. Drug vs. time curves for the comparison of orally administered methaqualone. Each point represents the mean ARCI scale score of each treatment at the five time levels (baseline to 4 hours post), adjusted from the analysis of covariance. Percent of maximum score is derived from the scale range (-30-96): (mean score/scale range) x 100. Below the plot are displayed the results of the post hoc drug by time ANCOVA at each time point, and the Neuman-Keuls contrasts indicating drug-placebo/drug-drug differences.

Treatment differences in the methaqualone study were highly significant by analysis of covariance (Table 1) at the $p < .001$ level for drug or drug-by-time or both on seven of the eight ARCI scales presented. The morphine group (MG) scale, designed to pick up characteristic effects of opiates, reached significance at the $p < .01$ level. Several of the measures, Sedation (Figure 1), Drunkenness (Figure 2) and PCAG (a scale to detect effects of pentobarbital, chlorpromazine, and alcohol group drugs) are measures of sedation or sedative-type intoxication. These scales did discriminate between 200 mg and 400 mg of methaqualone at the second and sometimes the third hour, showing the higher dose to be more sedative than the lower dose of methaqualone. On the Euphoria (Figure 3), Excitement, Amphetamine (Figure 4), and morphine-benzedrine group (MBG) scales, the two dosages of methaqualone were almost identical in the course and degree of drug effect with maximum effect occurring at 1 hour after drug ingestion.

In the prazepam-diazepam-placebo study (Table 2), main drug effects were less striking and drug-by-time interactions were more common, while significance levels were more modest than those seen in the methaqualone study. Sedative effects as measured by the Sedation (Figure 5),

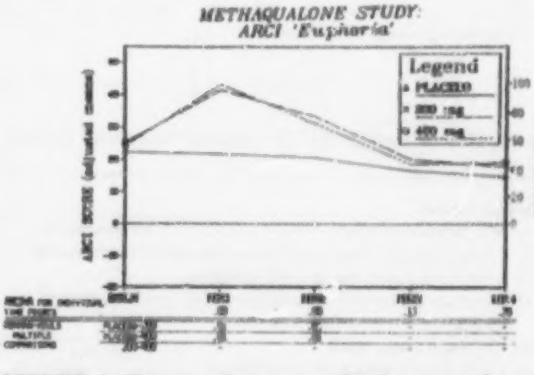

FIGURE 3. Drug vs. time curves for the comparison of orally administered methaqualone. Each point represents the mean ARCI scale score of each treatment at the five time levels (baseline to 4 hours post), adjusted from the analysis of covariance. Percent of maximum score is derived from the scale range (0-42): (mean score/scale range) x 100. Below the plot are displayed the results of the post hoc drug by time ANCOVA at each time point, and the Neuman-Keuls contrasts indicating drug-placebo/drug-drug differences.

Drunkenness (Figure 6), and PCAG scales were clearly significant. The sedation produced by both prazepam and diazepam in fact appeared equivalent to the 400 mg dose of methaqualone, while the degree of drunkenness produced by these agents was only comparable to the 200 mg dose range. Euphoriant effects were seen only on the Euphoria (Figure 7) and MBG scales, while a dysphoric effect was detected by the LSD scale.

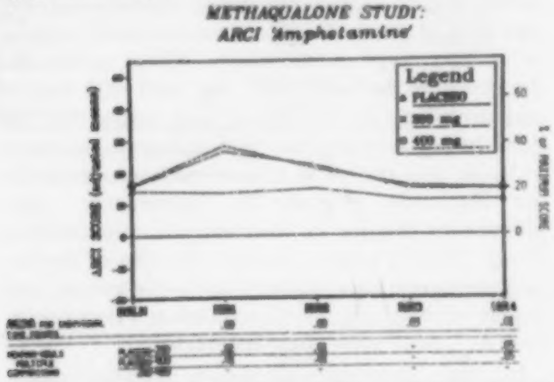

FIGURE 4. Drug vs. time curves for the comparison of orally administered methaqualone. Each point represents the mean ARCI scale score of each treatment at the five time levels (baseline to 4 hours post), adjusted from the analysis of covariance. Percent of maximum score is derived from the scale range (0-72): (mean score/scale range) x 100. Below the plot are displayed the results of the post hoc drug by time ANCOVA at each time point, and the Neuman-Keuls contrasts indicating drug-placebo/drug-drug differences.

Table 3

Items Contained in ARCI 'Abuse Potential' Scale

Positive Items:

1) My movements are free, relaxed, and pleasurable.
2) Things around me seem more pleasing than usual.
3) I am sure I will sleep well tonight.
4) I feel as if something pleasant had just happened to me.
5) My head feels light.
6) I feel a very pleasant emptiness.

Negative Items:

1) My face feels hot.
2) I feel as if I have the flu.
3) I feel like avoiding people, although I usually do not feel this way.
4) I have been getting cramps.
5) I have a feeling of just dragging along rather than coasting.
6) My head feels as it does during a hangover.

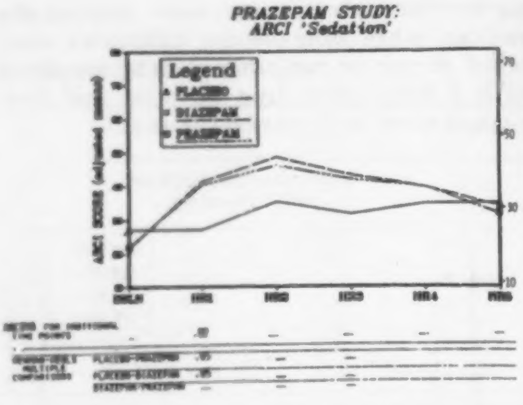

FIGURE 5. Drug vs. time curves for the comparison of orally administered prazepam and diazepam. Each point represents the mean ARCI scale score of each treatment at the six time levels (baseline to 5 hours post), adjusted from the analysis of covariance. Percent of maximum score is derived from the scale range (0-110): (mean score/scale range) x 100. Below the plot are displayed the results of the post hoc drug by time ANCOVA at each time point, and the Neuman-Keuls contrasts indicating drug-placebo/drug-drug differences.

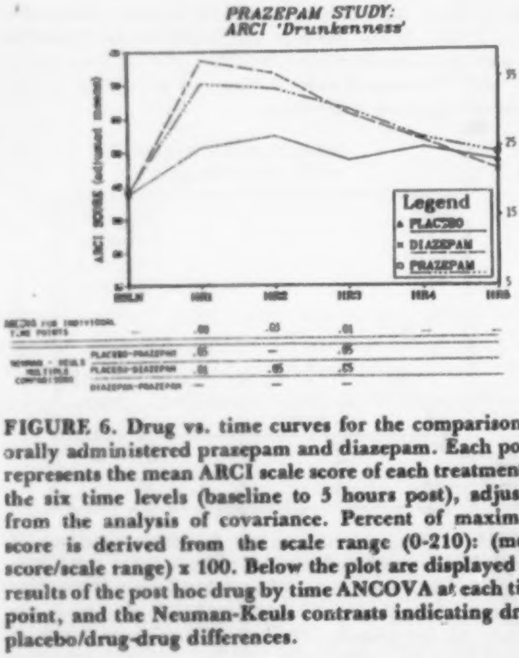

FIGURE 6. Drug vs. time curves for the comparison of orally administered prazepam and diazepam. Each point represents the mean ARCI scale score of each treatment at the six time levels (baseline to 5 hours post), adjusted from the analysis of covariance. Percent of maximum score is derived from the scale range (0-210): (mean score/scale range) x 100. Below the plot are displayed the results of the post hoc drug by time ANCOVA at each time point, and the Neuman-Keuls contrasts indicating drug-placebo/drug-drug differences.

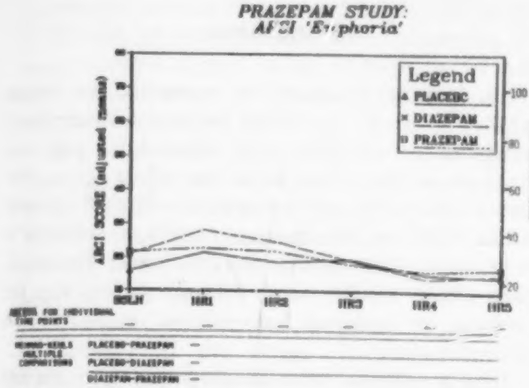
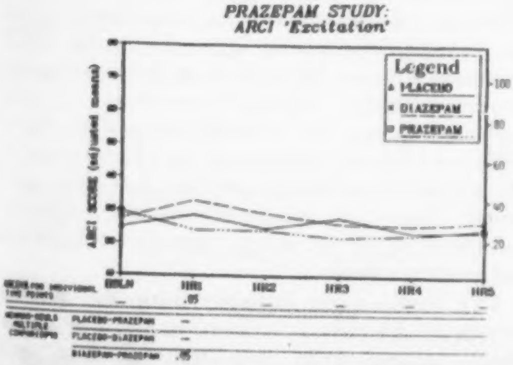
By Neuman-Keuls analysis, diazepam-placebo differences were seen at more time points on the sedative scales than were prazepam-placebo differences, suggesting a tendency toward a more sedative effect for 10 mg of diazepam than for 20 mg of prazepam. No Neuman-Keuls contrasts were significant on the Euphoria scale for either drug though diazepam, by inspection, appears to be a bit more euphoriant. On the Excitation scale (Figure 8), an unexpected significance level of $p = .05$ showing diazepam to be more "exciting" than prazepam at 1 hour was uncovered, but its statistical meaningfulness is reduced by the main analysis of covariance significance level (a $p = .09$ main drug effect).

We have created an artificial "Abuse Potential" scale from the ARCI based on items correlating with the price the subject would have paid for the drug dose he received at any given study session. These items are listed in Table 3. The correlations



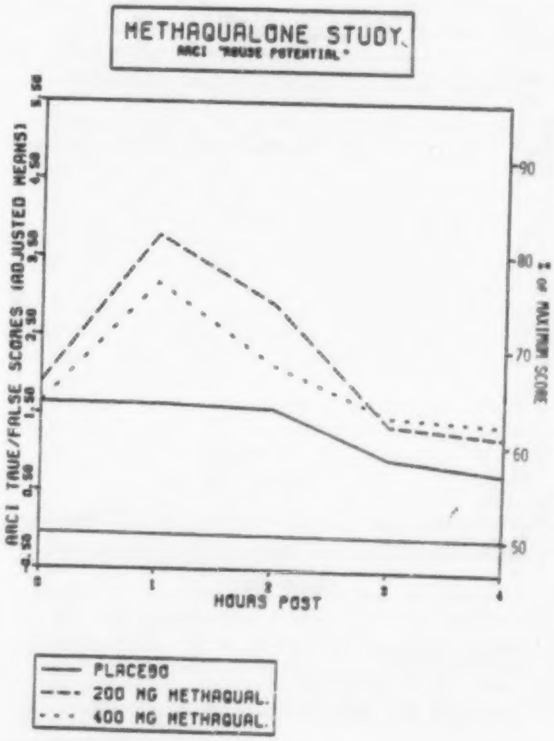
PRAZEPAM STUDY:
ARCI 'Euphoria'

FIGURE 7. Drug vs. time curves for the comparison of orally administered prazepam and diazepam. Each point represents the mean ARCI scale score of each treatment at the six time levels (baseline to 5 hours post), adjusted from the analysis of covariance. Percent of maximum score is derived from the scale range (0-70): (mean score/scale range) x 100. Below the plot are displayed the results of the post hoc drug by time ANCOVA at each time point, and the Neuman-Keuls contrasts indicating drug-placebo/drug-drug differences.



PRAZEPAM STUDY:
ARCI 'Excitation'

FIGURE 8. Drug vs. time curves for the comparison of orally administered prazepam and diazepam. Each point represents the mean ARCI scale score of each treatment at the six time levels (baseline to 5 hours post), adjusted from the analysis of covariance. Percent of maximum score is derived from the scale range (0-70): (mean score/scale range) x 100. Below the plot are displayed the results of the post hoc drug by time ANCOVA at each time point, and the Neuman-Keuls contrasts indicating drug-placebo/drug-drug differences.



METHAQUALONE STUDY
ARCI "ABUSE POTENTIAL"

FIGURE 9. Drug vs. time curves for the comparison of orally administered methaqualone. Each point represents the mean ARCI "Abuse Potential" score of each treatment at the five time levels (baseline to 4 hours post), adjusted from the analysis of covariance. Items were scored true/false to standardize values. Percent of maximum score is derived from the scale range (-6-6): (mean score/scale range) x 100.

(which had to reach ± .32 for statistical significance) were obtained from combining data from the methaqualone study described above and from a similar 24-subject study comparing 15 mg and 30 mg of dextro-amphetamine with placebo. By scoring the "Abuse Potential" items in the ARCI used in both the methaqualone and prazepam-diazepam studies true-false, we have been able to create comparable graphs for the two studies showing adjusted means on this measure (Figures 9 and 10). This measure showed highly significant drug-placebo differences for methaqualone ($p = .004$) and also showed the lower 200 mg methaqualone dose to be "preferred" to the 400 mg dose. This phenomenon is probably a function of the higher euphoria to sedation ratio in the 200 mg dose. Drug-placebo differences in the prazepam-diazepam study, however, were not statistically significant. Despite this, a visible tendency for diazepam to look more "abuse liable" than prazepam at the dosages studied is apparent.

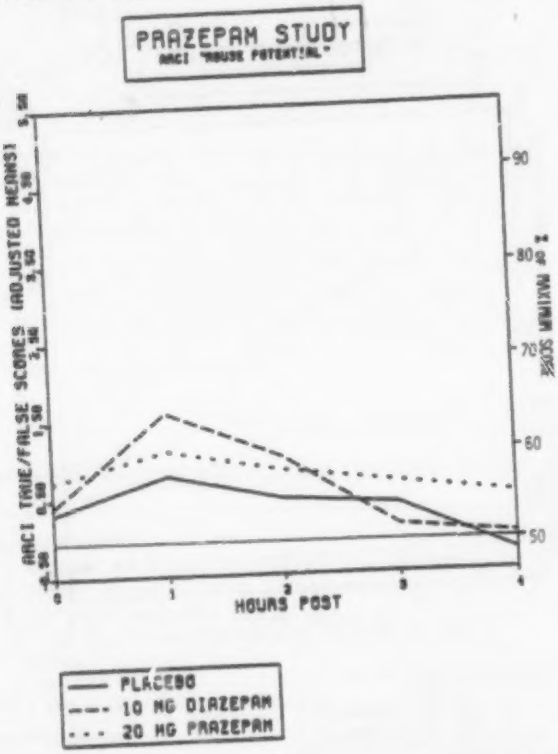


FIGURE 10. Drug vs. time curves for the comparison of orally administered prazepam and diazepam. Each point represents the mean ARCI "Abuse Potential" score of each treatment at the five time levels (baseline to 4 hours post), adjusted from the analysis of covariance. Items were scored true/false to standardize values. Percent of maximum score is derived from the scale range (-6-6): (mean score/scale range) x 100.

Discussion

The general approach to assessing the abuse liability of drugs described here, involving four groups of six subjects each selected for past experience in the recreational use of drugs in the class under study and the use of a reduced version of the ARCI as the main measure of subjective drug effects, is supported by the results obtained. Dose-effect results were obtained for methaqualone on sedative but not on euphoria-like measures.

Effects of the two benzodiazepines appear similar in direction but less in degree. Since only moderate clinical dosages were studied, the major questions about the abuse potential of benzodiazepines, as potentially measurable by our methodology, are not answerable. Very weak trends in the prazepam-diazepam data suggest that at higher doses of both drugs diazepam *might* be clearly more euphoriant. This possibility was strengthened by data presented by Jasinski (1981) in which a dose-response effect of both diazepam and chlordiazepoxide was obtained on the ARCI Sedation scale. Diazepam, but not chlordiazepoxide, showed dose-related increases on the ARCI Euphoria scale, suggesting that benzodiazepines may well differ among themselves in their euphoriant properties. A comparison of the effects of 20 mg of diazepam and 40 mg of prazepam in 12 recreational sedative users has just been completed. These data will be examined for differential effects of the two drug regimens on Euphoria and related scales.

The authors are also revising the scoring system for the ARCI. A factor analysis of 2-hour ARCI scores from our methaqualone and *d*-amphetamine studies has yielded three factors which measure euphoria, sedation, and dysphoria. These factors should provide clearer and, hopefully, more sensitive scales than the empirical ARCI scales we have been using. Jasinski et al. (1977) have used only the Sedation and Euphoria scales. Since PCAG and its subscale Sedation, and Drunkenness correlate between 0.76 and 0.96, while MBG and its subscale

Euphoria, Excitement, and Amphetamine correlate between 0.83 and 0.95, this limited assessment may be justified. The LSD scale, by contrast, seems to measure somatic and psychic dysphoria and correlates moderately well (0.46 to 0.70) with all other ARCI scales. It remains to be seen whether a new, factor analytic set of ARCI scales will be more sensitive or sensible than other approaches used to date.

The next difficult question is whether the system being used is a valid way of assessing the abuse liability of sedative drugs. It is unclear to what extent the benzodiazepines are actually abused, and the newer agents, such as prazepam, may not be abused at all. Illicit use probably reflects past and present popularity, as well as availability of the drugs. Methaqualone and diazepam are both known to illicit users, but prazepam may not be. After consideration of higher dose studies, the authors will be better able to assess the relative euphoriant and sedative qualities of benzodiazepines. If their methods do ultimately show methaqualone to have a higher euphoria/sedation ratio than diazepam, they will have more tangible data with which to characterize the abuse liability of the latter. Prazepam appears to be even less euphoriant than diazepam, and thus may be less liable to be abused. Illicit drug abuse as measured by epidemiologic surveys or law enforcement data may show a pattern of abuse popularity and/or frequency which reflects the trends observed in these studies. Unfortunately, good quality data on frequency of illicit use is lacking. At present, methods such as theirs are the most feasible approach to assessing the abuse potential of sedative drugs.

What Is the Effect of "Stress" on Neuroendocrine Function? In-Depth Consideration of Recent Theorizing

Chair: **Redford B. Williams, Jr., M.D.**
Duke University Medical Center
Durham, North Carolina

Heterogeneity in the Response Pattern of Organ Systems to Stress: Mediators and Mechanisms

Cynthia M. Kuhn, Ph.D.,[1] Alberto Grignolo, Ph.D.[1] Mark Johnson,[1] and Saul M. Schanberg, M.D., Ph.D.[1]

Ornithine decarboxylase (ODC, E.C.4.1.1.17) catalyzes the first step in the synthesis of the polyamines putrescine, spermidine, and spermine. This enzyme is an extremely useful index of cellular response to stimulation because its activity changes rapidly in response to numerous physiological events that affect the metabolic activity of the cell. In this laboratory, ODC has been used as a tool to characterize the effects of a number of hormones and neuroeffectors on tissue function, and to identify mediators of stress effects in developing and adult rats. Previous studies have shown that pharmacologic or physiologic stimulation of the sympathetic nervous system (SNS) by alpha or beta adrenergic agonists, insulin-induced hypoglycemia, or other simuli increases ODC activity in several organs including heart, kidney, liver, and aorta (Thadani & Schanberg 1979; Slotkin 1979; Grignolo et al. 1982). In the present study, the pattern of tissue ODC response to stress and neural and nonneural mediators of stress effects have been investigated. These studies show that ODC responses to stress are determined by the organ, age of the animal, and the type of stress.

Two hours of continuous immobilization (IMM) increase ODC activity in liver, heart, kidney, and aorta. However, with longer periods of IMM, a more complex pattern is observed. ODC activity continues to increase in kidney and liver, while heart ODC decreases. In contrast,

---

[1] Department of Pharmacology, Duke University Medical Center, Durham, NC 27710.

shaker stress, which has been reported to cause sympathoadrenal activation and hypertension in experimental animals (Bunag et al. 1980), causes a marked decrease in heart ODC activity but no change in kidney or liver ODC activity (Table 1). Interestingly, these stresses evoke different patterns of ODC response despite the fact that both cause a marked increase in serum levels of corticosterone (Table 2). Corticosterone is a potent inducer of liver and kidney ODC activity (Panko & Kenny 1971; Nicholson et al. 1976), yet ODC activity increased during IMM but not shaker stress, despite significant elevations in serum corticosterone during both stress paradigms. These findings suggest that some other physiologic response associated with these stress paradigms contributes to the regulation of ODC activity.

Table 1

Effects of Shaker Stress on Tissue ODC Activity

Organ	Control		ODC Activity (percent control)			
			2 hours		6 hours	
Kidney	100 ± 19	(47)	113 ± 20	(11)	111 ± 19	(18)
Heart	100 ± 35	(48)	95 ± 15	(10)	32 ± 5*	(18)
Liver	100 ± 18	(40)	107 ± 16	(9)	71 ± 5	(19)

Animals were shaken in a group at 175 oscillations/minute for 2 or 6 hours or left undisturbed in the home cage, then killed and tissue ODC activity determined. Results are expressed as percent control ± SEM. N is indicated in parentheses.

* Indicates statistically different from control activity, $p < .05$ or better. Control ODC activity = 0.68 nmole/g/hr for heart, 4.99 nmole/g/hr for kidney, and 0.185 nmole/g/hr for liver.

Table 2

Effect of Shaker Stress and Immobilization on Serum Corticosterone Concentration

	Corticosterone (ng/ml)	
Control	45 ± 11	(13)
IMM	338 ± 74*	(15)
Shaker	267 ± 34*	(15)

Animals were left undisturbed (control), immobilized in wire mesh cages or shaken in a group (175 oscillations/minute) for 4 hours, then killed and serum corticosterone determined by radioimmunoassay. Results are expressed as ng/ml ± SEM.

*Indicates statistically different from control, $p < .001$. N is indicated in parentheses.

The fact that stimulation of the sympathetic innervation elevates ODC activity in several peripheral tissues (Thadani & Schanberg 1979; Slotkin 1979) suggested that stress effects might be mediated neurally. This possibility was investigated by determining the effect of the ganglionic blocker chlorisondamine on the ODC elevation associated with IMM. Chlorisondamine markedly inhibited the increase in heart ODC associated with IMM in 26-day-old rats (Table 4). These results suggest that the ODC increase after IMM is mediated primarily by neural mechanisms and helps explain the discrepancy between serum corticosterone levels and ODC activity that is observed during IMM and shaker. The finding that the ODC increase associated with IMM could be almost completely blocked by chlorisondamine indicates that the marked corticosterone elevation which occurs during IMM does not significantly stimulate ODC activity. This finding further suggests that tissue ODC sensitivity to glucocorticoid hormones is altered during stress. Suppression of GH sensitivity during stress has already been reported (Kuhn et al. 1979).

An effect of stress that cannot be explained by SNS activation is the decrease in heart ODC which is observed during shaker stress and after long periods of IMM. Findings from other laboratories suggest that certain stresses including prolonged IMM can increase *vagal* activity (Fitzgerald 1975). To investigate this possibility, animals were pretreated with atropine, and then exposed to shaker stress. Atropine did not affect basal ODC activity, but almost completely prevented the decline associated with shaker stress (heart ODC values in shaker animals = 30 ± 7% of control, while values in atropine-treated animals = 84 ± 12% of control). These results indicate that vagal activity contributes to the decline in ODC associated with shaker stress, and suggest that the decrease in heart ODC activity that occurs after 6 hours of IMM might also reflect increased vagal tone to the heart.

The ODC responses to stress described above are not constant throughout an animal's lifetime, but change as the animal develops. ODC responsivity to stress in immature animals differs from that observed in adults in two ways. First, certain environmental stimuli change ODC activity in neonates, but not in adults. Second, the changes

Table 3

Effect on Stress on Tissue ODC Activity in Neonatal Rats

	Tissue ODC Activity (percent control)					
	Heart		Liver		Brain	
Control	100 ± 13	(35)	100 ± 24	(49)	100 ± 13	(14)
Maternal Deprivation	40 ± 9*	(57)	14 ± 4*	(48)	39 ± 3*	(15)
Deprived + Immobilized	101 ± 14**	(35)	98 ± 49**	(20)		
Deprived + Cold	151 ± 32**	(35)	140 ± 31**	(17)	70 ± 9**	(15)

Eight-day-old rat pups were deprived in an incubator, placed in an incubator in wire restraining cages, or placed in a 4° cold room for 2 hours. Controls were left with the mother for this time period. At the end of 2 hours, all animals were killed and tissue ODC activity was determined. Results are expressed as percent control ± SEM. *N* is indicated in parentheses.

*Indicates statistically different from control, $p < .05$ or better.

**Indicates statistically different from deprived animals, $p < .05$ or better.

Table 4

Effect of Chlorisondamine on ODC Activity During Immobilization

	ODC Activity (percent control)					
	Heart		Liver		Kidney	
Day 26						
Control	100 ± 13	(20)	100 ± 16	(18)	100 ± 17	(16)
Immobilized	297 ± 23*	(10)	277 ± 83*	(10)	1010 ± 300*	(9)
Chlorisondamine	85 ± 14	(20)	78 ± 16	(18)	162 ± 39*	(19)
Chlor + IMM	144 ± 21**	(10)	117 ± 11**	(10)	79 ± 20**	(10)
Day 10						
Control	100 ± 14	(8)				
Immobilized	171 ± 27*	(8)				
Chlorisondamine	106 ± 18*	(9)				
Chlor + IMM	200 ± 27*	(10)				

Animals were injected with saline or chlorisondamine, then immobilized for 2 hours in wire mesh cages and tissue ODC activity determined. Results are expressed as percent control ± SEM. *N* is indicated in parentheses.

*Indicates $p < .05$ or better relative to control.

**$p < .05$ or better relative to immobilized.

Control ODC activity = .295 nmole/g/hr for hearts on Day 26, 0.735 for Day 10. .238 nmole/g/hr for kidney and .399 nmole/g/hr for liver.

induced by classical stress paradigms are mediated by different physiological mechanisms in adults and neonates. Maternal deprivation (MD) of neonatal rats causes an immediate and long-lasting decline in ODC activity in most organs (Butler & Schanberg 1977). This decline is observed only in preweanling rats, and is initiated by the loss of a specific form of tactile stimulation of the pups by the mother (Butler & Schanberg 1977; Evoniuk et al. 1979). On the other hand, IMM or cold stress elevates ODC activity significantly in preweanling rat pups (Table 3). This finding suggests that maternal deprivation and the "classical" stress paradigms IMM and cold evoke distinct biochemical responses in developing rats. Furthermore, the heart ODC increase following IMM is not mediated neurally in pups, as chlorisondamine did not block stress effects in 10-day-old pups (Table 4). This finding is consistent with reports that functional sympathetic innervation of most peripheral organs is established between Days 12 and 16 postnatally (Slotkin 1979) and suggests that SNS activation is not the sole mediator of stress effects in developing animals.

These studies show that ODC responses to stress are a function of the type of stress, the organ, and the age of the animal. First, IMM and shaker evoke very different patterns of ODC response in adult rats, indicating that stress is not "nonspecific." Second, the sensitivity of a given organ to a hormone during stress appears to be modulated by concomitant changes in the activity of the autonomic nervous system and other endocrine systems. Furthermore, stress-induced secretion of certain hormones (e.g., corticosterone) does not necessarily lead to predictable biochemical responses in individual organs; that is, different tissue responses can be obtained in the presence of hormonal responses that are qualitatively and quantitatively identical. Third, certain stresses are effective only at certain maturational stages (e.g., maternal deprivation); others are effective at all ages but activate different effector pathways (e.g., neural vs. nonneural) depending upon the age of the animal and the maturity of those pathways.

Our studies of stress-induced changes in ODC activity suggest that this enzyme is an extremely useful tool for investigating hormonal and neural mediators of stress. By correlating ODC activity with endocrine and neural response patterns, we can obtain valuable information about the physiological responses of adult and immature animals to environmental challenges.

Correlation Between Pharmacological Activity and the Influence of GABA on the Binding of Flunitrazepam and the Specific Benzodiazepine Antagonist, Ro 15-1788[1]

Frederick J. Ehlert, Ph.D.,[2] William R. Roeske, M.D.,[2] Andrew Chen, B.S.,[2] and Henry I. Yamamura, Ph.D.[2]

Several lines of evidence indicate that gamma-aminobutyric acid (GABA) mechanisms are involved in the mediation of the pharmacological effects of benzodiazepines. The results of electrophysiological studies, for example, have shown that benzodiazepines potentiate the effects of GABA in a variety of neuronal systems (Tallman et al. 1980). Insight into the nature of the link between the pharmacological actions of benzodiazepines and GABA has come from biochemical experiments in which co-purification of GABA receptors and benzodiazepine receptors was demonstrated, and also from binding experiments in which GABA has been shown to enhance the binding of benzodiazepines (Olsen 1981). Results such as those described above have led to the suggestion that at least some benzodiazepine receptors are coupled to GABA receptor-chloride ionophore complexes. If the effects of GABA on the benzodiazepine receptor are related to the mechanism of action of benzodiazepines, then a correlation between the GABA modulation of binding and the pharmacological efficacy of a series of drugs which interact with the benzodiazepine receptor might be anticipated. Accordingly, we have found recently that GABA enhances the binding of the novel anxiolytic, CL218,872 (3-methyl-6-[3-trifluoromethylphenyl]-1,2,-4-triazolo[4,3-b]pyridazine) (Regan et al. 1981) but has little or no effect on the binding of presumptive pharmacological antagonist of benzodiazepines, propyl-carboline-3-carboxylate (Ehlert et al. 1981). Since a new class of compounds, the imidazodiazepines, have been reported to bind with high affinity to the benzodiazepine receptor and to antagonize selectively the pharmacological effects of tranquilizing benzodiazepines (Hunkeler et al. 1981), a quantitative study of the influence of GABA on the binding of the representative antagonist imidazodiazepine, Ro15-1788 (ethyl-8-fluoro-5,6-dihydro-5-methyl-6-oxo-4H-imidazo[1,5-a][1,4]benzodiazepine-3-carboxylate), might provide additional evidence for a correlation between GABA modulation of binding and pharmacological activity. In the present report, the results of such a study are presented and are shown to be consistent with the postulate that GABA enhances the benzodiazepine receptor binding activity of anxiolytics, like flunitrazepam (FLU), whereas the binding of benzodiazepine antagonists, like Ro15-1788, is largely insensitive to the influence of GABA.

Benzodiazepine receptor binding assays were carried out on the rat cerebral cortex using [^{3}H]FLU (83.6 Ci/mmole); the details of the assay have been given in a previous report (Ehlert et al. 1981). Briefly, cortical homogenates (20 mg original wet tissue weight/ml buffer) were washed five times by centrifugation and resuspension in fresh phosphate buffer (pH 7.4, 9.5 mM K$^+$, 81 mM Na$^+$, 50 mM PO$_4$). Binding was measured by the filtration method, and incubation lasted 30 min at 37°C.

Table

Effect of GABA on the Competitive Inhibition of [^{3}H]FLU Binding by FLU and Ro 15-1788

	IC_{50}[1]		IC_{50}control
	Control (nM)	10μM GABA (nM)	IC_{50} GABA
FLU (100 mM NaCl)	17.8	5.6[2]	3.2 (2.1 - 4.7)[3]
Ro15-1788	5.6	6.3	0.89 (0.64 - 1.2)
Ro15-1788 (100 mM NaCl)	7.1	6.3	1.1 (0.89 - 1.3)

[1] The IC_{50} represents the concentration of non-labeled drug that caused 50% inhibition of specific [^{3}H]FLU binding. Each IC_{50} value represents the geometric mean of values from four experiments.
[2] Significantly different from control, $p < 0.005$.
[3] 95% confidence limits.

The results of FLU/[^{3}H]FLU and Ro15-1788/[^{3}H]FLU competition experiments carried out in the presence or absence of GABA (10^{-5} M) are shown in the Table. In the presence of 100 mM NaCl, GABA caused a 3.2-fold reduction in the IC_{50} of FLU from 17.8 nM in controls to 5.6 nM in the presence of GABA. Since the concentration of [^{3}H]FLU (0.5 nM) used in the competition experiment was much less than the IC_{50} values, correction from IC_{50} to K_i led to negligible changes in the results. We have shown previously that in the absence of 100 mM NaCl GABA (10^{-5} M) only causes a 1.9-fold reduction in the IC_{50} of FLU at 37°C (Ehlert et al. 1981). In contrast, no significant effects of GABA (10^{-5} M) on the binding of Ro15-1788 were detected in the presence or absence of 100 mM NaCl (*see* Table). Identical results were obtained in the presence of 10^{-4} M GABA (data not shown).

The present results illustrate that under conditions in which GABA causes a moderate increase in the potency of FLU, no significant effects of GABA on the binding of the imidazodiazepine analogue Ro15-1788 are demonstrable. Since the results of pharmacological studies indicate that Ro15-1788 is a specific antagonist of tranquilizing benzodiazepines (Hunkeler et al. 1981), the present data are consistent with our previous suggestion that measurement of the influence of GABA on the binding of ligands to the benzodiazepine receptor may be a useful technique for determining if a drug has pharmacological properties agonistic or antagonistic to benzodiazepines (Ehlert et al. 1981).

Down Regulation and Heterogeneity of Opiate Receptors

Kwen-Jen Chang, Ph.D.,[1] and Steven G. Blanchard, Ph.D.[1]

One of the adaptative responses of cells or neurons to chronic exposure to ligands is regulation of receptor number. While for most polypeptide hormones and some neurotransmitters the receptor number is decreased after chronic ligand treatment, for the opiate receptor no alteration of receptor numbers after chronic opiate treatment in animals has been observed despite the development of opiate tolerance and dependence. The investigators reexamined this phenomenon in a simple system, the cultured neuroblastoma cell.

Cultured mouse neuroblastoma cells (N4TG1) serve as a useful model for studies on the molecular and cellular action of opiates and opioid peptides (Chang et al. 1978; Chang & Cuatrecasas 1979). Direct receptor binding studies with a labeled enkephalin analog on neuroblastoma cells did not indicate internalization of opiate receptors since nearly all cell associated label was dissociated as intact molecules (Chang et al. 1978). Using the fluorescent enkephalin analog, rhodamine-conjugated [D-Ala^2,Lys^6] leu-enkephalin and image-intensified fluorescence microscopy, enkephalin (δ) receptors in neuroblastoma cells were found to slowly form clusters which do not appear to be internalized (Hazum et al. 1979a,b, 1980). This result differs from many polypeptide (hormones) receptors (*see* review by Hazum et al. 1981) such as for insulin, epidermal growth factor, nerve growth factor, α_2-macroglobulin, chemotactic peptide, and gonadotropin releasing hormone, in which the receptors are internalized following the initial receptor-ligand interactions. This internalization is believed to be related to the so-called down regulation or desensitization.

Chang et al. (1982b) reported that after one to several hours' exposure of neuroblastoma cells in monolayer culture to enkephalin, the number of enkephalin receptors measured subsequently in the extensively washed membrane preparations is greatly reduced. This action is referred to as down regulation. This reduction in receptor number seems selective for opioid peptides and is antagonized by a variety of opiate agonists and antagonists.

Confluent monolayers of cultured mouse neuroblastoma cells (N4TG1) were pretreated with ligand, the cells were then washed extensively with phosphate buffered saline (PBS) to remove ligand remaining bound, and membrane particulate fractions were prepared and washed again with Na+-containing buffer to dissociate any remaining ligand. The enkephalin receptor binding was then measured with ^{125}I-labeled [D-Ala^2, D-leu^5] enkephalin (DADLE) on those cell membrane particulate preparations. Similar results were also obtained when [^{3}H]DADLE or [^{3}H]diprenorphine was used as labeled ligand. Pretreatment of the cell monolayer for 4 hours with 0.1 μM DADLE led to a large reduction of the binding activity of labeled ligands. This reduction induced by the DADLE pretreatment is time, temperature, and dose dependent (Chang et al. 1982b). At 37°C, significant reduction was observed after half-hour pretreatment, and had nearly reached maximum (about 80% reduction) after 1 hour. At 24°C, this reduction in binding is greatly decreased with respect to both the rate and the extent of reduction. The DADLE-induced down regulation is dose dependent with an EC_{50} value of about 2 nM. This value is in reasonable agreement with the previously determined dissociation constant (K_d) of DADLE for enkephalin receptor of this cell line (Chang et al. 1978; Chang & Cuatrecasas 1979).

Down regulation induced by DADLE is specific for opiate receptors, since this effect can be antagonized by the presence of an excess of opiate antagonists such as naloxone, nalorphine, and diprenorphine (Figure 1A). These antagonists do not induce down regulation when they are present alone (Figure 1A). The natural endogenous peptides, met- and leu-enkephalin as well as β-endorphin, and their metabolically stable analogs [D-Ala^2,NMePhe^4,Met(O)ol^5] enkephalin (FK 33824) and [D-Ala^2,Met^5] enkephalinamide can also induce similar down regulation at concentrations of less than μM.

Morphine and benzomorphan drugs such as ketocyclazocine, a κ-agonist, and N-allylnormetazocine, a σ-agonist, at high concentrations induce only a slight and nonsignifi-

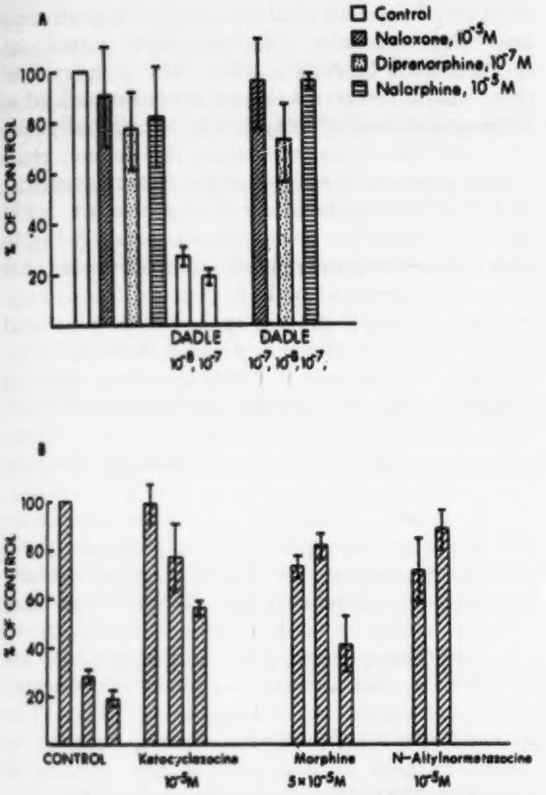

FIGURE 1: Specificity of the ligand-induced opiate receptor down regulation.

N4TG1 cells were grown to confluence in DMEM supplemented with 75 units/ml penicillin, 75 μg/ml streptomycin sulfate and either 7 or 5% newborn calf serum (GIBCO) in a 95% air/5% CO_2 humidified atmosphere at 37°. Cells were incubated with or without various opiate agonists (B) and antagonists (A) in the absence and presence of DADLE as indicated in the figure for 4 hours at 37°C. After completion of the incubation the medium was withdrawn, the monolayers rinsed with PBS and the cells were detached using 0.05% EDTA in PBS. The cells were pelleted by centrifugation, resuspended in PBS and incubated for 30 minutes at 37° to remove bound ligand. This incubation was repeated once and then the cell pellet was resuspended in ice cold 50 mM Tris, pH 7.7, and the cells were homogenized using a Model PT-20 Polytron (setting 3.5, 20 sec). The homogenates were centrifuged at 40,000 xg for 30 minutes and the resulting pellets were resuspended in 50 mM Tris, pH 7.7, containing 100 mM NaCl and the suspensions were incubated at room temperature for 1 hour. The membranes were again pelleted, resuspended, and pelleted once in Tris buffer lacking sodium, and assayed for ^{125}I-DADLE binding.

cant receptor reduction (usually about 20%). They can also antagonize the effect of opioid peptides (Figure 1B). This antagonistic effect of opiates against peptides is also dose dependent. Opiates are more effective against a dose of 10^{-8} M than of 10^{-7} M DADLE, as would be expected for competitive inhibition (Figure 1B).

Incubation of cell monolayers with 10^{-8}M [^{3}H]DADLE at 37° for 4 hours followed by washing and preparation of membrane particulates in manner identical to that used for the nonradioactive ligand showed that only 10 percent of the ligand initially associated with the cells remained bound. This corresponds to a concentration of DADLE of less than 10^{-10}M in the final assay. Because incubation of cells with the 10^{-8}M DADLE caused about 70 percent down regulation, the loss of binding activity could not simply be attributed to the competition of ^{125}I-DADLE with ligand that remained after preparation of the membrane fragments. Furthermore, diprenorphine, a ligand known to have an affinity greater than DADLE (Chang et al. 1980), does not cause significant receptor reduction after similar pretreatment, suggesting that peptide-induced receptor loss could not be simply explained by the high affinity of the ligand that may not be washed away.

The enkephalin-induced binding reduction is manifested by a decrease in the number of high affinity binding sites, presumably enkephalin (δ) receptors. The Scatchard plots of the saturation binding curves of ^{125}I-DADLE for control and DADLE (0.1 μM) pretreated cell membranes revealed the loss of total high affinity binding sites without changing the slope (Figure 2). Thus, binding sites remaining after DADLE pretreatment have an affinity similar to that of the control membranes. This is further confirmed by the competition binding studies of DADLE and morphine against ^{125}I-DADLE binding. No significant difference in IC_{50} values (the concentrations which cause 50 percent inhibition of labeled binding) between control and pretreated membranes was observed (Chang et al. 1982a). IC_{50} values of about 50 nM for morphine and 1 nM for DADLE were observed for both control and pretreated membranes in agreement with previously reported values (Chang & Cuatrecasas 1979; Chang et al. 1978, 1979).

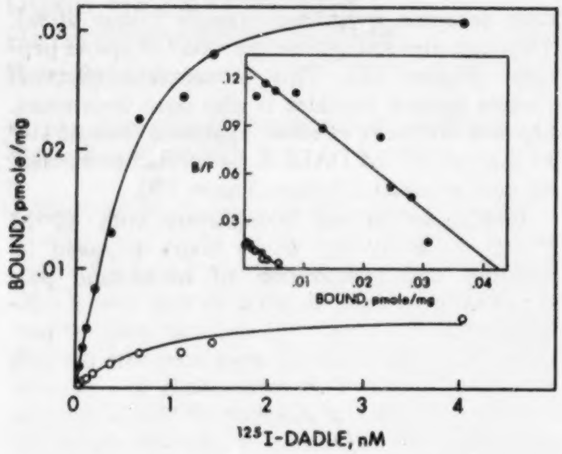

FIGURE 2: Binding of ^{125}I-DADLE to N4TGl membranes before and after preincubation of cells with unlabeled DADLE.

Confluent cultures of N4TGl cells were incubated with or without 10^{-8}M unlabeled DADLE and membranes were prepared as described in the legend to Figure 1. Aliquots of the membranes were incubated for 1 hour with various concentrations of ^{125}I-DADLE after which time bound ligand was determined by rapid filtration through glass fiber filters. Nonspecific binding was determined in the presence of 10^{-5}M unlabeled DADLE. Plots of control (●) and treated (O) membranes are shown. *Inset:* Scatchard plots of the data are shown. The control membranes had a Kd of 0.76 nM and B_{max} of 42.8 fmol/mg while the values for the treated membranes were 0.83 nM and 6.4 fmol/mg, respectively.

The decrease in receptors specifically induced by opioid peptides is intriguing. Numerous *in vivo* and *in vitro* experiments have indicated that enkephalin can mimic the biological effects of morphine, including the development of tolerance and physical dependence (Wei & Loh 1976). To our knowledge, the present results are the first demonstration of opiate receptor down regulation and appear to contradict the conventional concept. Opioid peptides, but not opiate alkaloids, induce down regulation. It will be interesting to know whether this selective effect for opioid peptides is due to the particular opiate receptor subtype in neuroblastoma cells or to neoplastic properties of this cell line. It also will be interesting to know whether the same effect can be observed in the other subtypes of opiate receptors.

Currently it is believed that there are at least five opiate receptor subtypes (Chang & Cuatrecasas 1981). There are $\mu,\varkappa,\sigma,\delta$, and ϵ receptors based on pharmacological experiments and four receptor binding sites based on radioreceptor binding studies. The properties of these opiate receptor subtypes are summarized as follows: $\mu,\varkappa$, and σ receptors were originally proposed by Martin to account for the distinct pharmacological actions of morphine, ketocyclazocine, and N-allylnormetazocine. For μ-receptor, morphine is a selective prototype μ-agonist. A highly selective μ-receptor peptide, morphiceptin, has also been identified to be a peptide fragment of β-casein, a major protein in cow milk (Chang et al. 1981a). Kosterlitz, Paterson, & Robson (1981) and others (Handa et al. 1981) have also obtained a highly selective peptide ([D-Ala^2,NMePhe^4, Gly^{5}ol]enkephalin) for μ-receptor. Either μ-Receptors predominate in guinea pig ileum or the intrinsic activity of μ-receptor in guinea pig ileum is greater. Naloxone is a potent antagonist. Mu-receptors are predominately localized in brain areas associated with analgesia and sensory functions (Goodman et al. 1980). They may mediate analgesic and cataleptic activities in animals (Chang et al. 1982a). The possible existence of μ_1 and μ_2-receptors has also been suggested recently by Pasternak (1981). The μ_1-receptor is inhibited irreversibly by naloxazone treatment both *in vivo* and *in vitro* (Zhang & Pasternak 1981; Wolozin & Pasternak 1981).

For $\varkappa$-receptors, ethylketocyclazocine (EKC) is the typical $\varkappa$-agonist. Recent data from Wüster et al. (1980) and Chavkin and Goldstein (1981) have suggested that dynorphin may serve as a natural ligand for $\varkappa$-receptors. Mouse vas deferens and guinea pig ileum tolerant to μ- and δ-agonists do not show tolerance to dynorphin. High cross tolerance occurs between the typical $\varkappa$-agonists and dynorphin. These receptors show less antagonistic sensitivity to naloxone. They may mediate sedation in animals and hallucinatory and dysphoric effects in man.

Although it was originally postulated that σ-receptor is a subtype of opiate receptor (Gilbert & Martin 1976), the data currently available suggest that it may be a non-opiate type receptor. The typical hyperactivity caused by σ-agonists, is not antagonized by naloxone, only the (+) stereoisomer is active and the effects resemble those of phencyclidine. In studies on stimulus-discriminative procedure, Herling and Wood (1981) showed that rats trained to discriminate phencyclidine generalize to σ-agonists such as

N-allylnormetazocine and cyclazocine. Furthermore, using binding studies, several laboratories (McLowhon et al. 1981; Zukin & Zukin 1981) have also provided evidence that perhaps the σ-agonists bind to the phencyclidine binding sites in addition to their opiate receptor activities.

Delta-receptors were proposed by Lord et al. (1977) to account for the high potency of enkephalin in mouse vas deferens. Many available cultured neuroblastoma cells also contain homogenous δ-receptors (Chang & Cuatresasas 1979). Naloxone is known to be less active in this system than in the μ-receptor system. Delta-receptors are predominately located in the limbic system, as shown by Goodman et al. (1980), and may mediate the action of epileptic seizures (Frenk et al. 1978a, 1978b; Liebeskind 1978) and possibly the reward behavior described by Stein and Belluzzi (1978) and other affective actions of opiates.

Schulz et al. (1979) proposed ϵ-receptors to account for the unusual selective potency of β-endorphin in rat vas deferens. In this system, both enkephalin and morphine are poor ligands. Interestingly, κ-agonists such as ethylketocyclazocine, bremazocine, and MR2034 behave as rather potent competitive antagonists (Huidoboro et al. 1980; Gillan et al. 1981).

Biochemical receptor binding studies utilizing highly specific radioisotope labeled ligands have confirmed at least three topographically distinct opiate receptor binding sites in brain (Chang et al. 1981b). They are opiate alkaloid morphine preferring binding sites, peptide enkephalin preferring binding sites, and binding sites selective for benzomorphan drugs. Morphine binding sites represent μ-receptors which can be studied with low concentrations of [^{3}H]-labeled dihydromorphine, naloxone, naltrexone or ^{125}I-labeled FK 33-824. Enkephalin binding sites labeled by low concentrations of labeled enkephalins and DADLE are δ-receptors. After quenching μ and δ-receptors with a μ-agonist, morphiceptin and a δ-agonist, DADLE, [^{3}H]diprenorphine binds to a third opiate receptor which we call benzomorphan binding site (Chang 1981). Excluding σ-receptor as an opiate receptor, at present, it is still not clear whether the benzomorphan binding site corresponds to κ or ϵ receptors, since both have similar high affinity for benzomorphan drugs and low affinity for enkephalin and morphine. Kosterlitz et al. (1981) and Pfeiffer and Herz (1981) have claimed that a similar κ-binding site is identified by using [^{3}H]EKC. However, etorphine which is believed to have no κ-agonist activity has high affinity for this [^{3}H)EKC binding site. Beta-endorphin also shows high affinity compared to enkephalin. It remains to be established whether benzomorphan binding sites are identical to the κ-binding sites.

Using ^{125}I-labeled [D-Ala^2]β_h-endorphin, Hazum et al. (1979c) have reported the existence of a non-opiate but β-endorphin specific binding site. A similar non-opiate β-endorphin specific binding has also been observed in a neuroblastoma cell line N18TG2 by Hammonds and Li (1981) who use [^{3}H]labeled β-endorphin.

Previous *in vivo* morphine chronic experiments have led to the conclusion that neither the number nor the affinity of receptors are altered after chronic treatment with morphine (Pert et al. 1973; Klee & Streaty 1974; Hölt et al. 1975; Simon & Hiller 1978). Similar experiments to measure the binding activities of three subtypes of opiate receptors including morphine (μ), enkephalin (δ), and benzomorphan binding sites after chronic morphine treatment *in vivo* have been carried out in this investigator's laboratory. The results confirmed the previous conclusion that neither the number nor the affinity of any opiate receptor subtype are altered after chronic morphine treatment. Thus, the effect of reducing receptor numbers may be selective for opioid peptides and differ from the phenomena of *in vivo* morphine tolerance and dependence.

However, the recent demonstration of the lack of cross-tolerance between a δ-agonist (DADLE) and a μ-agonist (sulfentanyl) in mouse vas deferens after chronic *in vivo* treatment with either ligand (Schulz et al. 1980) suggests that tolerance selective for a receptor subtype may occur in certain systems. N4TG1 cells contain δ-receptors only. The present studies demonstrate that only opioid peptides induce the down regulation of enkephalin receptors. Morphine (a μ-agonist), ketocyclazocine (a κ-agonist), and N-allylnormetazocine (a σ-agonist) are ineffective in inducing this effect. In fact, they antagonize the effects of opioid peptides. These observations resemble the studies on mouse vas deferens (Schulz et al. 1980). Selective desensitization due to the loss of opiate receptors may develop for δ-receptors after chronic opioid peptide treatment for certain systems. The previous failure to detect the change of opiate receptors after chronic treatment may be because peptides have not been used.

There are many possible mechanisms for the ligand-induced loss of receptors reported here. For instance, desensitized low affinity receptors may be induced by peptides which can no longer be detected by the present binding method. Our preliminary experiments suggest that this is not the case. It may also be possible that the receptors are cryptic after treatment with opioid peptides. The formation of (essentially) irreversible receptor-ligand complexes may also occur during the pretreatment. Understanding of the mechanism of receptor reduction may have important implications for understanding the physiological, pharmacological, and pathological actions of opioids.

Alpha Adrenergic Receptor Subtypes: Physiological Relationships and Mechanisms

Brian B. Hoffman, M.D.[1]

Alpha adrenergic receptors have been grouped into two major subtypes, termed alpha$_1$ and alpha$_2$ receptors. Radioligand binding techniques have been utilized to measure the number of alpha$_1$ and alpha$_2$ receptors in a variety of tissues. [^{3}H]dihydroergocryptine labels the entire alpha receptor population; the alpha receptor subtypes may be delineated by constructing competition curves with unlabelled selective antagonists and analyzing the data with computer modeling techniques (Hoffman et al. 1979). Alternatively, alpha$_1$ and alpha$_2$ receptors may be directly identified with selective radioligands such as [^{3}H] prazosin and [^{3}H]yohimbine.

Using these methods, human platelets have been found to contain alpha$_2$ receptors (Hoffman et al. 1979). Rabbit uterus contains both alpha$_1$ and alpha$_2$ receptors. Studies in intact strips of rabbit uterus demonstrated that catecholamines induced smooth muscle contraction by activating alpha$_1$ receptors; alpha$_2$ receptors do not seem to play a direct role in this response (Hoffman et al. 1981). Estrogens increase the number of alpha receptors in the uterus; interestingly, this change occurs exclusively in the alpha$_2$ receptor population which is not involved in mediating contraction. Rat liver membranes contain both alpha$_1$ (80%) and alpha$_2$ (20%) receptors (Hoffman et al. 1980b). In isolated hepatocytes, the alpha$_1$ receptors mediate glycogen phosphorylase activation, whereas the physiological significance of the alpha$_2$ receptors in liver is unclear. In experiments designed to study the regulation of alpha receptors, it is important to delineate the subtypes rather than merely the total number of receptors since alpha$_1$ and alpha$_2$ receptors may mediate distinct physiological effects and be separately regulated.

Alpha$_1$ and alpha$_2$ receptors seem to have quite distinct mechanisms of action, although the molecular details for neither receptor are well understood. $Alpha_1$ receptors have been associated with changes in intracellular calcium metabolism in a variety of tissues; $alpha_1$ receptors have not been found to regulate intracellular cAMP concentration. $Alpha_2$ receptors have been found to inhibit adenylate cyclase activity in a host of cells. The inhibition of adenylate cyclase is dependent on the presence of GTP. Perhaps related to the different mechanisms of the two receptors is the observation that GTP regulates the affinity of agonists such as epinephrine at $alpha_2$ receptors but not at $alpha_1$ receptors. Indeed, radioligand binding studies have shed some light on the mechanism of $alpha_2$ receptor function. Agonist competition curves with [^{3}H]dihydroergocryptine at the human platelet's $alpha_2$ receptor may be resolved into two affinity components, interconvertable by guanine nucleotides (Hoffman et al. 1980a). These data suggest the possibility of an agonist-promoted association of the $alpha_2$ receptor with an additional membrane component. More direct evidence in favor of this possibility was demonstrated by the increase in sedimentation velocity of solubilized agonist labeled receptor on sucrose density gradients, compared to either unoccupied or antagonist labeled receptor (Michel et al. 1981). A future area of active investigation will involve efforts to further characterize this component which presumably leads to the inhibition of adenylate cyclase.

Retrospective Report of Premenstrual Depressive Changes: Factors Affecting Confirmation by Daily Ratings[1]

Jean Endicott, Ph.D.,[2] and Uriel Halbreich, M.D.[3]

Daily ratings made across one or more menstrual cycles at times confirm, and at other times fail to confirm, premenstrual changes reported by women on retrospective questionnaires (Abplanalp et al. 1980; Dalton 1964; Golub 1974; May 1976; McCance et al. 1937; Sampson & Jenner 1977). The authors have begun a series of studies to help determine 1) which types and levels of severity of reported premenstrual changes are most likely to be confirmed by daily ratings; 2) the most efficient ways of obtaining such ratings; and 3) the possible consequences of a failure to confirm reported changes when selecting subjects for biological or treatment studies.

Retrospective Reports of Premenstrual Changes. All subjects described their usual premenstrual changes during the prior three cycles on the Premenstrual Assessment Form (PAF). The PAF, described in detail elsewhere (Halbreich et al. in press), is a 95-item questionnaire designed to describe premenstrual changes with a greater degree of specificity than that of other available procedures (Moos 1968; Steiner et al. 1980). The PAF items are scored to obtain summary measures of 7 Bipolar Continua, 18 Unipolar Dimensional Scales, and 18 Typological Categories. After completion of the PAF, the women made daily ratings for at least one menstrual cycle. A PAF was also completed at the end of the cycle over which daily ratings were made with the focus upon the premenstrual period just experienced.

This preliminary report focuses only upon the typological category of "Depressive Syndrome." The criteria, presented in abbreviated form, are: A. – Depressed or low mood (one of five items rated at least mild), or irritable mood (one of two items rated at least mild); and B. – If depressed mood, at least four of eight items, if irritable or loss of interest or pleasure only, at least five of the eight items. The eight items report change in appetite, sleep, psychomotor function, anergia, loss of interest, low level of social activity, self-deprecation, concentration difficulties, and suicidal ideation.

Daily Ratings. After completing the PAF, the women begin making daily ratings on 21 items of particular interest in ongoing studies by the authors. Each item is rated on a scale of 1 for "not present at all" to 6 for "extreme" manifestation of the mood or behavior in question.

Activity Monitors. Two types of premenstrual depressive syndrome are of particular interest to the authors, that with hypersomnia, lethargy, and decreased activity level, and that with anxiety and increased activity level. Large-scale integrated

(LSI) activity monitors (McPartland et al. 1975) are worn by some subjects when they are making daily ratings in an attempt to obtain objective measures of activity level across the cycle.

Subjects. The subjects were participating in a number of different studies and were recruited in varying ways. Some were co-workers of the senior author, others responded to notices posted about the medical center seeking women for studies across the menstrual cycle, and others contacted the investigators as a result of a newspaper article and a television program reporting on the authors' interest in premenstrual changes. Many of the women in the latter groups were seeking treatment or referral for treatment. At the time of the ACNP meeting, 48 women had completed daily ratings across at least one menstrual cycle, in addition to the initial PAF.

Results

Range of Severity. Women responding to posted notices and co-workers of the senior author tended to report fewer changes and changes of much lower levels of severity than women seeking treatment.

Agreement Between Pre- and Post-PAF. Although the pattern of reported changes was similar for the two PAFs, the severity ratings completed after the cycle of daily ratings tended to be lower. For example, on the PAF Summary Scale for Depressed Mood and Ideation, the mean on the pre-PAF was 26 and that on the post-PAF was 23. The number of subjects whose PAF ratings met criteria for Major Depressive Syndrome pre was 41 and post was 27. The severity levels of the daily ratings also tend to be lower than those noted on the pre-PAF. Some women commented afterward that their premenstrual changes had not been as severe as expected. Both of these findings suggest that women may tend to describe their "worst case" when they report on premenstrual changes in the absence of special attention having been paid to them during the prior month or months.

Likelihood of Confirmation of Depressive Syndrome by Daily Ratings. Confirmation required that the average daily ratings on specified items be at least two points higher during the premenstrual than during the postmenstrual period. Furthermore, ratings during the nonpremenstrual days should not be indicative of a tendency to have frequent depressive changes throughout the cycle.

The overall rate of confirmation of the presence or absence of a premenstrual depressive syndrome was only 59 percent for the total sample of 48 women. Fifteen women reported severe depressive changes on the pre-PAF, 13 of these were confirmed, while only 6 of the 14 who reported moderate depressive changes and 5 of the 12 who reported depressive changes at the mild level were confirmed. The pre-PAF ratings for 7 women indicated that they did *not* meet the criteria for a premenstrual depressive syndrome. Their daily ratings confirmed such an absence in only 4, while 3 of the 7 were found to have depressive changes of a syndromal type at the mild level. Two of these women commented on this spontaneously, indicating that they had not noticed premenstrual depression previously. Thus, the likelihood of confirmation of either the presence or absence of a premenstrual depressive syndrome was clearly related to the severity of the reported change, with high levels of confirmation limited to those reporting a severe syndrome.

Although some of the women whose ratings failed to confirm reports of mild or moderate change had daily ratings indicating premenstrual depressive changes on some items, the number of items and level of severity of change were not sufficient to confirm a clear syndromal change of a depressive nature.

The major reason for a lack of confirmation for the women who described severe or extreme changes were ratings indicative of frequent or chronic depressive symptoms throughout the cycle. Although some of these women had premenstrual exacerbations on some items, there was not a clear difference in level of severity for the entire syndrome.

Confirmation of Changes in Activity. Although only a few subjects have worn the LSI, it is already apparent that reported changes of activity may or may not be confirmed. Some women report lethargy, but are actually more active premenstrually. Others report hypersomnia, but are not less active when they are awake. Daily ratings and LSI readings are given for one subject in which both measures confirmed the retrospective reports made on the PAF (*see* Figure).

Example of Confirmation of Reported Premenstrual Changes of Depression, Mood, and Reduced Activity Level

Discussion

The preliminary findings have clear relevance for studies of premenstrual changes, particularly biological and/or treatment studies.

Subjects should not be selected on the basis of retrospective reports alone, whether they are chosen to have particular types of changes or to be free of them. Daily ratings made across one or more cycles are needed to confirm such reports. This is particularly true for changes of a syndromal nature. Reports of changes in activity levels should also be objectively confirmed through the use of activity monitors.

A possible explanation for the high rate of "placebo" response in treatment studies for premenstrual dysphoria is the rather consistent finding that women report less severe changes after at least one cycle of careful attention to their moods and behavior. Had the women involved in the current studies been on placebo, the scores on the second PAF would have "indicated" that they had a "placebo response." Thus it is not only advisable to use daily ratings to confirm reported changes, but also to establish a new baseline against which placebo or active treatment response may be judged.

Many studies of daily ratings which have reported a lack of confirmation of premenstrual changes have used college students or volunteers who have not been seeking treatment. The levels of severity reported by such women are usually minimal, mild, or moderate. The relationship between level of severity and likelihood of confirmation found in the current study suggests that this may have been a major reason for the low level of confirmation in such studies.

Another reason for lack of confirmation is that many women who reported premenstrual changes of a depressive nature also had depressive symptoms frequently throughout the month so that the premenstrual period was not clearly different.

Some investigators interview women at two points in their cycle to determine if they are clearly more depressed premenstrually than during midcycle. Unfortunately, in the absence of daily ratings, the conclusions drawn from contrasting the two interviews may be misleading if the aim is to select women who are relatively free of depressive symptoms during the nonpremenstrual days of the cycle. Some women appear to have a few days to a week during midcycle when they feel better and are depressed most of the remaining days, with some worsening premenstrually.

The degree to which other nondepressive changes are confirmed by daily ratings is also under study. The findings reported here, as well as those of prior investigators, strongly support the need for the use of daily ratings and other measures of premenstrual change if one is attempting to select homogeneous groups of subjects with contrasting types of changes and levels of severity. Questionnaires such as the PAF are best used for screening of subjects.

During its earliest years, this unit focused on identifying differential response tendencies among young men taking neuroleptics. Promising typologies were developed to predict, for example, contrasting responses in extroverted athletic men and rather more introspective aesthetes, and in men differing in anxiety traits. These differences seemed to arise from both constitutional and psychological predilections. We were intrigued by the possibility that some of our procedures might be applied to young women, perhaps differentiated in terms of their athletic background. Very soon, however, we were obliged to recognize that for many women, within-month variation in (especially affective) symptomatology was greater than any expectable neuroleptic effect in healthy volunteers. As part of our attempts to identify women with more pronounced tendencies to experience these exaggerated emotional shifts, we found ourselves embarked on a series of studies of the premenstrual tension syndrome.

A 55-symptom checklist was constructed following a review of the literature available at that time (1966). Together with three rating scales of impairment in physical, emotional, and task/social functioning, it was administered to 457 healthy, young women not currently using oral contraceptive medication (Table 1). Rating scale distributions were superimposed and cut-off criteria established for distinguishing between women who experienced minimal and maximal premenstrual tension symptoms across the domain of their somatic and affective lives. These groups are subsequently referred to as the minimal and maximal groups. A residual group was acknowledged as inconsistent with regard to this distress. Indeed, among the maximal group, five prevalent symptoms, viz. anxiety, irritability, depression, fatigue, and abdominal distension were determined regularly to co-occur (Table 2). Such co-occurrence suggested that these symptoms comprise the basis of a premenstrual syndrome (Table 3). A series of multivariate procedures, including obverse factor analysis and discriminant function analysis, were subsequently carried out to identify some five major patterns of premenstrual experience among our volunteers: Group 1 was characterized mostly by depression and irritability; Group 2 by depression and breast enlargement; Group 3 by abdominal pain and autonomic symptoms; and Group 4 by reduced energy, irritability, weight gain, and abdominal distension. Group 5 was nearly symptom-free.

The authors then undertook to relate selected biochemical and treatment parameters to their understanding of premenstrual tension as differently experienced by especially the minimal and maximal groups of women. Inspired by the early work of Loraine and Bell (1963), they examined urinary progesterone and estrogen in 18 healthy, normally ovulating women. Fractionated estrogens (estrone, estriol, estradiol) were determined by the method of Brown (1955) Pregnanetriol was assessed using the procedure of Fotherby and Love (1960). Klopper's Method (1955) was used for pregnanediol. Ten women had self-ratings that met the minimal premenstrual tension criteria and eight were maximal. For the analysis, complete data were available in 13 cases. Their cycles were divided into follicular and luteal phases by subtracting 15 days from the lengths of their cycles. Temperature records confirmed the occurrence of ovulation during the study month.

Table 4 shows lower luteal pregnanediol levels for the maximal cohort. Table 5 illustrates an essentially bimodal distribution of pre-ovulatory estrogen with significant differences between the two cohorts. In Table 6 luteal pregnanediol is shown to differ according to level of pre-ovulatory estrogen. This last observation is consistent with Dalton's demonstrations that natural progesterone is an effective treatment for premenstrual tension syndrome.

Although plasma MAO had earlier been studied for its relationship to premenstrual tension, the authors wanted to understand platelet MAO activity through the cycles of women contrasted for their characteristic premenstrual experience. For 1 month, on alternate days, blood was drawn from 11 high and 10 low premenstrual tension women. Belmaker (1974), who used similar biochemical procedures, collected the data shown in Figure 1. Figure 2, however, illustrates that when the data were separated according to premenstrual cohort, the authors found a follicular decrement for our low group and a luteal increment for the high group. On the average, on paper-and-pencil measures, the high premenstrual group evidenced greater dysphoric tendencies during both phases of their cycles.

FIGURE 2

With regard to treatment, staff was encouraged by open trials with lithium to undertake a controlled trial of lithium among women who met their premenstrual tension criteria (i.e., members of the MAXIMAL cohort). (*see* Figure 3.) They set out to study 60 healthy women, evenly assigned to receive either lithium carbonate (900 mg/day), placebo, or Dyazide (triamterene 100 mg and hydrochlorothiazide 50 mg/day). Each woman was screened over the course of a preliminary cycle and then, in the next or treated cycle, was evaluated before and after her follicular and luteal weeks. The test battery included standard measures of anxiety, depression, and hostility, as well as self-ratings of functional capacity. Over 60 percent of the screened applicants had to be dropped by the end of the first cycle because of health or procedural anomalies, menstrual cycle irregularities, inconsistent premenstrual experience. In other words, the program was tedious to carry out, and when after 13 women had been run on each active drug condition, as well as 10 on placebo, and no consistent or statistically significant benefit was observed on any measure, the study was terminated.

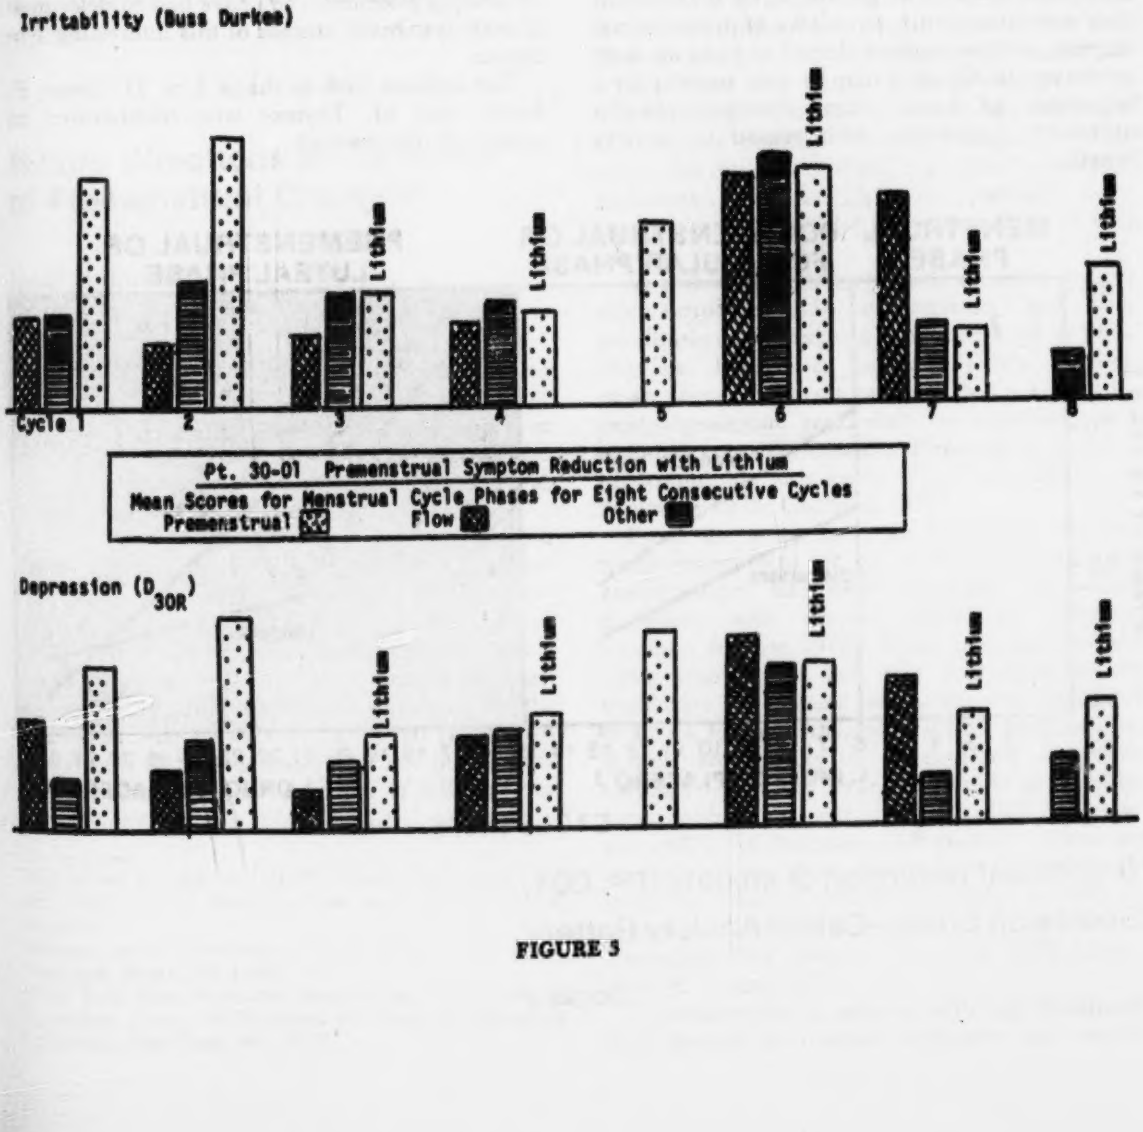

FIGURE 3

In a study of diazepam, 6 mg/day, the authors burdened themselves with an even more cumbersome selection strategy, but with more fortunate results. In this design, they tried to stratify by premenstrual criteria, and by level of anxiety trait to allow comparability with previous work with young men. Considerable overlap obtained between self-reports of premenstrual tension and indices of neuroticism like anxiety. They found it inordinately difficult to find subjects with low anxiety who consistently experienced high premenstrual tension. Forty-nine subjects were stratified by anxiety level and then evaluated on measures of anxiety, depression, and hostility. Only 13 of these cases proved to be invariant in their month-to-month experience of premenstrual distress, and the authors elected to focus on their responses. In Figure 4 may be seen support for a hypothesis of luteal phase diazepam/placebo superiority, especially with regard to anxiety benefit.

The investigations have generally confirmed that menstrual cycle effects might be an important source of variance in psychotropic drug and biochemical trials, especially when female subjects are predisposed to these molimina. It is also true, however, that we have found conventional factorial designs too impractical to fulfill. Their current preference is to include in a multivariate consideration, like a regression equation, a variable which can index a given proband's susceptibility, i.e. which is coded "yes" if the case characteristically suffers from premenstrual tension and whose experimental trial happens to involve her luteal phase. Otherwise, with changes in funding priorities, they have had to defer most of their systematic studies of this interesting syndrome.

The authors wish to thank Drs. D. Osser, P. Soloff, and M. Taymor who collaborated on aspects of this research.

Future Directions in the Study of Premenstrual Changes[1]

Uriel Halbreich, M.D.,[2] and
Jean Endicott, Ph.D.[3]

The physical, behavioral, and mood changes which may occur during the premenstrual period are very prevalent and sometimes may be severe enough to warrant treatment. However, the etiology and pathophysiology of premenstrual changes (PMC) are unclear.

A recent wave of interest in PMC has been manifested by an increase in the number of articles and symposia on the subject. Many of these share a widely held misconception in that the entire gamut of premenstrual changes is treated as a single syndrome. Studies by the authors (Halbreich & Endicott 1982; Halbreich et al., 1982b, 1982c) as well as others (Moos & Leiderman 1978) have indicated that PMC are better conceived as consisting of a number of different but partially overlapping subtypes and dimensions.

Subtypes of PMC are differentially related to affective disorder (Endicott et al. 1981), even among women who meet criteria for a premenstrual depressive syndrome. Three subtypes of premenstrual depressive changes have been shown to have different external correlates (Halbreich et al., in press). Furthermore, some of the major types of change are bipolar (e.g., decreased and increased activity or appetite, depression but also elevation of mood).

Once the concept of a single PMC syndrome is replaced by a recognition of diverse PMC whose subtypes should be delineated and well-defined, the door is open to change the assumption that a single variable is responsible for "a premenstrual tension syndrome." It is highly unlikely that such diverse changes with evidence of differential correlates have the same pathophysiology. The diversity of PMC should lead to the assumption of multivariate etiology of these changes. Furthermore, the division of PMC into specific subtypes facilitates study of different, partially overlapping, mechanisms of pathophysiology of each subtype.

An imbalance between some hormones, especially estrogen and progesterone, has been previously suggested as a causative factor of PMC (Review: Rausch & Janowski 1982). Furthermore, there is indirect evidence that a high estrogen/progesterone ratio may be associated with irritability-anxiety-hostility PMC as opposed to predominantly depressive PMC (Bäckström & Mattsson 1975; Cullberg 1972).

From the other side, an imbalance between neurotransmitters (e.g., norepinephrine and acetylcholine) has been suggested in mental disorders with similar syndromes (Review: Pradhan & Bose 1978). Brain monoamines and other transmitters not only participate in the regulation of gonadal hormones, but there are feedback mechanisms, influence on metabolic enzymes, and effects on postsynaptic sensitivity through which the ovarian steroids actively interact with neurotransmitters (Rausch & Janowski 1982). In humans and animals, there are several reports that plasma, urine, and brain levels of neurotransmitters or their metabolites fluctuate along the menstrual cycle (Weiner & Elmadjian 1962; Deleon-Jones et al. 1978; Greengrass & Toung 1971).

It is reasonable to assume, with high likelihood, that changes in ovarian hormones and several neurotransmitters are involved in an intricate interactive balance whose impairment may be part of the pathophysiology of PMC. Moreover, there has recently been a substantial accumulation of data suggesting that various functions of the central nervous system are modulated by, or at least involve, a growing number of recently discovered substances, various endogenous opioids, prostaglandins, i.e., trace amines. A possible role of some of these substances in PMC has been hypothesized (Halbreich & Endicott 1981; Reid & Yen 1981; Horrobin 1979). These hypotheses were based on the fluctuations of the relevant substances along the menstrual cycle, their possible involvement in phenomenology that resembles PMC, and their interaction with gonadal hormones and neurotransmitters.

[3] New York State Psychiatric Institute and Department of Psychiatry, College of Physicians and Surgeons, Columbia University, New York, NY 10032.

One may hypothesize that multiple interactions exist among all the above-mentioned systems (and probably some others) which influence each other. Such an interaction may be in an imbalance during the premenstrual period. The imbalance may be triggered by a succession of events which take place prior to, and during, the premenstrual period. This period may be defined as a period of *change*. Indeed, a premenstrual change in plasma levels or activity may be the only common denominator for the numerous substances whose involvement in the PMC has been hypothesized. In most cases premenstrual changes in levels of hormones and other substances, by themselves are normal, but the magnitude and pace of change vary substantially among women.

One may assume that when levels of several hormones (and other substances) change simultaneously, but at differing pace and magnitude, the homeostasis between hormones, modulators, and neurotransmitters may be temporarily impaired. As a consequence of this impaired homeostasis, vulnerability to external and internal stimuli are increased and greater imbalance may ensue. The imbalanced system is also susceptible to wide fluctuations which may be caused by minor changes in one or several of its components.

Such a model may provide an explanation for the diversity of premenstrual changes. Specific symptoms may be caused by a) changed activity of a single compound in the system; b) a change in an entire system (e.g., renin-angiotensin-aldesterone) which c) may be amplified by a simultaneous change in other compounds or systems (e.g., water retention may be caused by increased activity of the renin-angiotensin-aldesterone axis which may be further aggravated by increased acetylcholine activity which by itself causes increased secretion of antidiuretic hormone). Increase in other variables like prolactin may also contribute to the severity of the same results, namely, water retention; or d) impaired balance between two or more systems (e.g., various monoamines, endorphins, ovarian hormones, etc.) may cause change by itself.

A shift from a conceptual framework of a single causative factor to a multivariate imbalance hypothesis has immediate implications for future studies of PMC. Different strategies of research should be implemented.

The search for different biological mechanisms underlying the various clusters of PMC is self-explanatory. Women with different subtypes of PMC should be compared to each other; comparisons should not be limited to those with no changes at all. Determination of fluctuations in endogenous levels of hypothetical participating variables during the premenstrual period are interesting, but the yield is questionable (especially in plasma) unless the dynamic multiple balance between them is measured. Repeated measurement of dynamic multiple balance and its relationship to mental and behavioral changes in the same women during sequential premenstrual periods and under different environmental conditions may yield valuable information on the interaction among biological changes, vulnerability, and the environment. Dynamic intervention studies (which will not be listed here) may also result in more sophisticated information.

Indeed, a successful approach to the testing of a multivariate imbalance hypothesis of the pathophysiology of PMC necessitates a multidisciplinary team which will completely depart — conceptually and operationally — from the outdated dichotomy between "psychological" and "biological" changes. A multivariate time-sequence statistical analysis should be applied to the data. It is needless to say that an objective, nonbiased (to both sides) investigation should replace the highly prejudiced approach that is still so prevalent in menstrually related research.

Methylphenidate in Adults with MBD Symptomatology

Jeffrey A. Mattes, M.D.,[1] Lane Boswell, B.A.,[2] and Herman Oliver, M.D.[2]

The fate of children with minimal brain dysfunction (MBD) is uncertain. Until recently, it was believed that children outgrow the symptoms of MBD around the time of puberty (Eisenberg 1966). Recent studies, however, indicate that the outcome of children with MBD is not universally positive. Family (Cantwell 1975) and followup (Weiss et al. 1971) studies suggest that hyperactive children are at risk for behavioral difficulties, including alcoholism and sociopathy, past puberty; though the symptom of hyperactivity may decrease, distractibility, impulsivity, excitability, low self-esteem, poor academic achievement, and interpersonal difficulties may continue into later life. There are also preliminary data suggesting that stimulant medication may be effective in adult conditions possibly related to childhood MBD (Wood et al. 1976; Wender et al. 1981). However, these studies did not include a control group, and so were not able to determine the specificity of drug effect.

The objectives of this study were to evaluate whether methylphenidate (Ritalin), a standard treatment for childhood MBD, is effective in adults with symptoms considered related to MBD, and to evaluate the specificity of drug response. The overall goal was to determine if MBD is a specific diagnostic entity in adulthood with a specific treatment, i.e., stimulant medication.

Method

All patients applying to an adult psychiatric outpatient clinic (approximately 3,000 patients during the course of this study) were screened by questionnaires and interviews to determine eligibility. Two groups of patients were identified: 1) an experimental patient group with adult symptoms of MBD (restlessness, poor concentration, emotional lability, and impulsivity) and retrospective diagnoses of childhood MBD (more specifically, MBD with hyperactive symptomatology), and 2) a control group with similar adult symptoms but with no childhood histories of MBD (this controlled for the possibility that methylphenidate is helpful for certain adult symptoms regardless of childhood history).

It was assumed that the control group would manifest adult MBD-like symptomatology as a result of anxiety or depression; however, severe depressives (major depressive episodes of greater than mild severity), schizophrenics, and manic depressives were excluded. All patients were entered into a double-blind, crossover design, and given 3-week trials of methylphenidate (up to 60 mg/day; the actual mean dosage was 48 mg/day) and placebo.

Baseline evaluation included ratings by patients, psychiatrists, and significant others, on MBD-related and other symptomatology. In addition, old school records were obtained, and parents were asked to retrospectively rate the patient's childhood MBD symptomatology and neuropsychological testing. Evaluation of drug effect included ratings by patients, psychiatrists, and significant others.

Results

Final results, with an *N* of 63 (approximately 30 in each group) are as follows:

The Diagnostic and Statistical Manual-III (DSM-III) diagnoses of the two groups did not differ significantly except, as expected, that the experimental group much more frequently met the criteria for attention deficit disorder, residual type. The most common diagnoses were major depressive disorder (mild in severity; $N = 19$), alcohol abuse ($N = 17$), drug abuse ($N = 16$), borderline personality disorder ($N = 16$), generalized anxiety disorder ($N = 7$), and antisocial personality disorder ($N = 5$).

A number of baseline measures differentiated the two groups. The experimental group (with childhood hyperactivity) began drinking heavily at an earlier age. Those who did drink heavily had histories of more drug abuse, had missed more time from work, had more conflicts with others, had more childhood antisocial symptoms, and did worse on the Tactual Perception Test. These differences were in the expected direction and indicate that we were successful in identifying relatively distinct groups.

Unfortunately, however, the groups did not differ significantly in response to medication (the principal analyses were four-way analyses of variance: drug x group x order x sex). There was a slight tendency for the experimental group to be judged as having improved more on methylphenidate than the control group, but statistically significant differences were rare.

Attempts to identify predictors of drug response were generally unsuccessful. Correlations between the baseline measures and improvement on methylphenidate were, for the most part, nonsignificant; of the few significant correlations with greater improvement, some were in the expected direction (e.g., more drug abuse and more childhood vandalism), but others were in the opposite-than-expected direction (e.g., fewer temper outbursts and less retrospective parent-rated childhood hyperactivity). Analyses comparing "improvers" on methylphenidate vs. "non-improvers" were also generally unsuccessful in identifying predictors of drug response. In particular, retrospective parent ratings of childhood hyperactivity, reported by Wender et al. (1981) to predict stimulant responsiveness, did not predict response in our sample. Subdividing patients according to the certainty of childhood diagnosis of hyperactivity, or according to the presence or absence of significant depression or anxiety, did not assist in the attempt to identify a homogeneous group of methylphenidate responders. Of the suggestive positive findings, history of drug abuse (polydrug) seemed to be the best predictor of positive methylphenidate response; also, psychiatrist ratings of hyperactive symptomatology tended to predict stimulant response (in the expected direction) more frequently than did ratings by patients, parents, or "significant others."

Despite the generally negative results, we were impressed that a few patients (about 10 in the total sample) did appear to obtain clinically meaningful benefit from the methylphenidate (but not from placebo); these patients had a variety of DSM-III diagnoses. For these patients methylphenidate was recommended clinically following this study, and several of these patients followed this recommendation and continued to benefit from methylphenidate (periodic trials off mediation confirmed this benefit). The response to methylphenidate in some of these cases was as dramatic as in the case histories reported by Wood et al. (1976) and Wender et al. (1981).

Discussion

This study failed to find evidence of methylphenidate response among adults with symptomatology suggestive of MBD. No baseline measure, including history of childhood MBD, predicted methylphenidate response. The clinical evidence of response in certain patients was not evident statistically, and is therefore basically anecdotal. It appears that further work should be done to identify predictors of stimulant response among adults with MBD symptomatology.

Lithium and Haloperidol in Hospitalized Aggressive Children[1]

Magda Campbell, M.D.,[2] Arthur M. Small, M.D.,[2] Wayne H. Green, M.D.,[2] Susan J. Jennings, M.A.,[2] Richard Perry, M.D.,[2] Walter G. Bennett, M.D.,[2] Maria Padron-Gayol, M.D.,[2] and Lillian Anderson, R.N.[2]

The purpose of this clinical trial was to assess critically the relative efficacy of haloperidol and lithium in children diagnosed as conduct disorder with a behavioral profile of aggressiveness and explosiveness.

Both lithium and haloperidol have antiaggressive properties in adult psychiatric patients with symptoms of aggressiveness and explosiveness (Shopsin et al. 1975; Sheard et al. 1976; Tupin et al. 1973).

There has been little if any systematic investigation of the efficacy of psychoactive drugs involving large samples of aggressive children (for review, *see* Campbell et al. 1978, 1982). This is in spite of the fact that the most frequent reason for admitting children into psychiatric hospitals is repeated occurrences of disruptive and highly explosive behaviors. These children often fail to respond to psychosocial types of interventions and require placement into residential treatment centers.

Method

Sixty-one (57 males, 4 females) hospitalized children, ages 5.2 to 12.9 years (mean, 8.97) who met the Diagnostic and Statistical Manual (DSM-III, 1980) criteria of conduct disorder, undersocialized, aggressive, completed this double-blind, placebo-controlled study. The following criteria were used for patient selection: 1) a behavioral profile which consisted of severe aggressiveness, explosiveness, and disruptiveness unresponsive to various outpatient treatments including pharmacotherapy and which resulted in the current psychiatric hospitalization; 2) no evidence of psychosis; and 3) no evidence of mental retardation. In addition, the child had to have 1) laboratory values within normal limits; 2) no history of medical illness or no current medical illness contraindicating administration of psychoactive drugs; 3) no seizure disorder or administration of antiepileptic drugs; 4) no need for concurrent administration of any type of drugs; 5) discontinuation of any psychoactive drug for a minimum of 2 weeks prior to the beginning of administration of study medication; 6) meeting the criteria of the Aggression Checklist developed by Hardesty and Shopsin (unpublished); and 7) written informed consent from the child's parents or legal guardians.

On admission to the hospital various examinations, including physical and laboratory tests, were performed on the children. Birth and hospital records were obtained whenever feasible. Family history of psychiatric illness and pre- and perinatal complications were recorded on a scale developed in the authors' unit (Campbell 1977); in addition, the Rochester Research Obstetrical Rating Scale (ROS) (Zax et al. 1977) was completed.

The experiment lasted 6 weeks. All children were placed on placebo for 2 weeks in order to 1) carry out baseline assessments, and 2) eliminate the placebo responders. Children who were suitable for the study were randomly assigned to one of the three treatment conditions: haloperidol, lithium, or placebo. Throughout the study, starting with the first day of the 2-week placebo baseline period, children received three capsules t.i.d. or nine capsules daily. All capsules contained 0.5 mg or 2.0 mg of haloperidol, or 250 mg of lithium carbonate, or placebo. All capsules

were identical in appearance. The medication was administered by the research nurse at 8 a.m., 12 noon, and 4 p.m.

Increments in drug dosages were carried out according to a fixed and coded schedule. Haloperidol dosage began at 1.0 mg/day; increments were gradual over a period of 2 weeks until a maximum of 16.0 mg/day was reached or until the development of untoward effects required reduction or stabilization of dosage. Lithium dosage began at 250 mg/day; increments were made in a similar fashion. The maximum dosage was not to exceed 2,000 mg/day and/or a blood level of 1.8 mEq/l. Dosage was individually regulated over a period of 2 weeks and was followed by a 2-week period on optimal dose. Lithium levels in saliva (Shopsin et al. 1969) were monitored twice a week throughout the study and in blood at termination.

Behavioral symptoms, cognitive functioning, untoward effects and electroencephalograms (EEGs) were assessed on baseline and during treatment at fixed points. Ratings were carried out under several rating conditions by multiple rates using multiple rating scales.

The following measures from the Early Clinical Drug Evaluation Unit (EDCEU) Assessment Battery (*Psychopharmacol. Bull.*, 1973) were used: The Children's Psychiatric Rating Scale (CPRS), Clinical Global Impressions (CGI), Conners Teacher Questionnaire (CTQ), Conners Parent-Teacher Questionnaire (PTQ), Dosage Record and Treatment Emergent Symptoms (DOTES), and the Treatment Emergent Symptom Scale-Write In, using a checklist of untoward effects. In addition, two scales developed by the authors and their staff were employed: a Timed Aggression Behavioral Checklist (ABC), and Global Clinical Judgment.

Results

Several demographic variables were examined to reveal possible influences on drug effectiveness, optimal dose, and outcome. These demographic variables were: socio-economic status (Hollinshead 1965), weight, age, sex, IQs (full scale, verbal, and performance), race, and total score from the ROS. The three treatment groups were compared using chi-square and one-way analyses of variance, which showed no differences between treatment groups at baseline on any of the measures. This precludes the possibility that drug related differences were confounded by these variables among treatment groups.

For children who received haloperidol the optimal doses ranged from 1.0 to 6.0 mg/day (mean, 2.95), or 0.04 mg/kg/day to 0.21 mg/kg/day (mean, 0.096). The maximum dose given during the regulation period ranged from 1.5 to 12.0 mg/day. The optimal doses of lithium ranged from 500 to 2,000 mg/day (mean 1,166). On these doses, lithium level in saliva ranged from 0.81 to 5.05 mEq/l (mean, 2.515); this corresponded to 0.32 to 1.51 mEq/l (mean 0.993) in serum. The maximum doses of lithium given during the regulation period ranged from 750 to 2,000 mg/-day (mean 1,452).

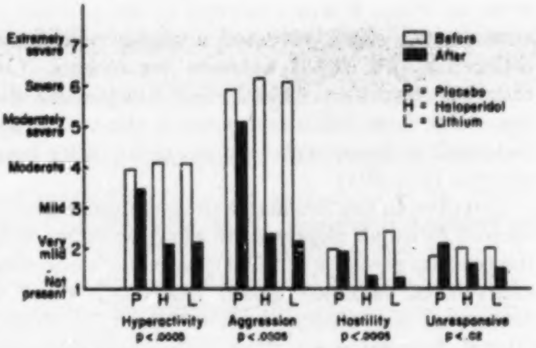

FIGURE 1. Ratings of two child psychiatrists on the Children's Psychiatric Rating Scale, before and after treatment.

Twenty-three CPRS items were entered into an average-linkage clustering analysis which yielded five clusters: Aggression, Hyperactivity, Unresponsive, Hostility, and Speech Problem. In addition, the items tension and bedwetting were also included in subsequent analyses. The details of the cluster analyses will be reported elsewhere. Week 6 ratings for the five clusters and two items were analyzed by an analysis of covariance to determine whether drug significantly affected these areas of behavior. The results are shown in Figure 1. The Hyperactivity cluster (which contained symptoms of hyperactivity, fidgetiness, and distractibility), Aggression cluster (fighting with peers, temper outbursts, and bullying), and Hostility cluster (negative-uncooperative, angry affect, loud voice, and lability of affect) showed highly significant drug effecs ($p < .0005$); the Unresponsive cluster (underproductive speech, and unspontaneous relation to examiner also showed a significant drug effect ($p < .02$). Speech Problem (level of speech development and mispronunciations), tension, and bedwetting, however, did not show significant drug effects.

Orthogonal contrasts used to compare haloperidol with lithium and to compare haloperidol and lithium with placebo on the four clusters yielded significant differences from baseline to treatment. In each case the two drugs did not differ from each other, but did differ from placebo for the Hyperactivity, Hostility, Aggression ($p < .001$), and Unresponsive clusters ($p < .01$).

The first item of the CGI scale, severity of illness, at Week 6 was analyzed by an analysis of covariance, which revealed a highly significant difference ($p < .0005$) between treatments. Orthogonal contrasts showed that haloperidol did not differ from lithium; however, the two drugs did result in improved ratings and did differ from placebo ($p < .001$).

Children in the two active drug conditions were viewed as much improved in contrast to those in the placebo group ($p < .0005$), based on a one-way analysis of variance which examined Week 6 ratings of the second item of the CGI Scale, Global Improvement. The differences between the two active drug conditions and placebo condition were significant ($p < .001$), but there were no significant differences between the active drugs.

The Efficacy Index is two dimensional, requiring an assessment of both therapeutic effects and side effects. The therapeutic effect differed significantly across conditions ($p < .00005$). Haloperidol did not differ from lithium, but these two differed from placebo ($p < .001$) by orthogonal contrasts. There was also a significant difference among treatment conditions for side effects ($p < .03$) due to the fact that haloperidol has (on optimal dose) more side effects than placebo or lithium which do not differ from each other.

The 39 items of the CTQ were rated by three teachers. Analysis of covariance showed no significant differences among treatment groups for any cluster or individual item. However, only 30 percent of the behaviors improved on placebo while 80 percent improved on haloperidol or lithium.

The PTQ scale was completed by the head nurse of the ward. The Week 6 data were analyzed by an analysis of covariance. Although no significant differences were found, there was a tendency for lithium to be more effective than haloperidol which in turn was more effective than placebo. Behavior actually worsened or remained the same on placebo, but improved in the two drug conditions.

The ABC scale yielded no significant results.

After each child completed the study he was rated on the Global Clinical Judgment Scale as unchanged or worse, minimal, moderate, or marked improvement. This rating was a result of a joint agreement of all staff, while still blind to the child's actual treatment condition. A highly significant difference ($p < .00005$) resulted from a one-way analysis of variance of these scores, as shown in Figure 2, indicating that children treated with haloperidol or lithium improved moderately in contrast to children who received placebo. Orthogonal contrasts confirmed that haloperidol does not differ significantly from lithium, but both lithium and haloperidol differed significantly from placebo ($p < .001$).

Untoward effects were recorded both during dosage regulation and optimal dose (*see* Table). All 20 children who were receiving haloperidol have shown untoward effects at some point: excessive sedation (15; 4 of these on optimal dose), acute dystonic reaction (10; none on optimal), drooling (6; one of these on optimal), and tremor

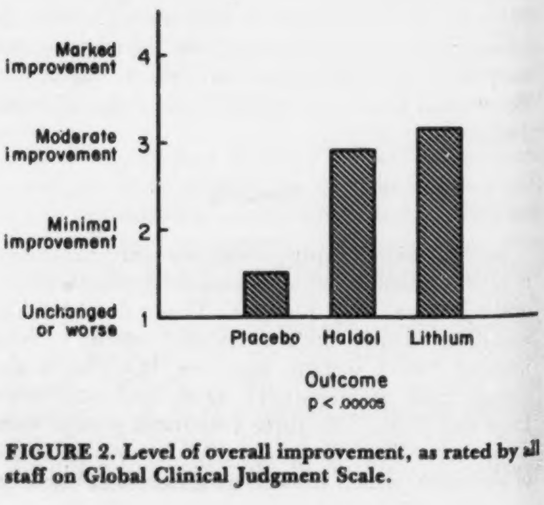

FIGURE 2. Level of overall improvement, as rated by all staff on Global Clinical Judgment Scale.

Table

Incidence of Untoward Effects* by Drug in 61 Patients

Untoward Effects	Haloperidol	Lithium	Placebo	Total
Excessive Sedation	15 (4)	–	4 (3)	19 (7)
Acute Dystonic Reaction	10	–	1 (1)	11 (1)
Tremor	5	5 (3)	1 (1)	11 (4)
Stomachache	–	7 (3)	2	9 (3)
Headache	–	6 (2)	–	6 (2)
Drooling	6 (1)	–	–	6 (1)
Other	18 (4)	25 (5)	6 (4)	49 (13)
TOTAL**	54 (9)	43 (13)	14 (9)	111 (31)
No. of Patients	20	21	20	61
No. of Patients with Untoward Effects	20	17	10	47

*On optimal dose in parenthesis

**Total number of occurrences of different untoward effects

(5; none of these on optimal) were most commonly observed. Of the 21 children assigned to lithium, 17 had untoward effects: pains in the stomach (7; 3 of these on optimal), headache (6; 2 of these on optimal), and tremor (5; 3 of these on optimal dose) were most frequent. In the 20 children who were receiving placebo, 10 patients had some type of untoward effect: excessive sedation (4; 3 of these on optimal dose) and worsening of aggressiveness (4; 3 on optimal) were most common.

During the optimal dose period the average number of untoward effects per child in each of the three treatment conditions did not differ significantly. However, the untoward effects of haloperidol during optimal dose seemed to interfere more with the child's daily functioning than those seen with lithium or placebo. The number of untoward effects on optimal dosage decreased with age on haloperidol ($r = -.40$, $p = .039$), but not lithium.

The cognitive battery and EEG data are currently being analyzed.

In summary, both lithium and haloperidol were superior to placebo in reducing target behaviors in hospitalized aggressive and explosive conduct disorder children on certain measures. The therapeutic effect of these drugs is not only statistically significant but also clinically meaningful.

However, these findings should be replicated. Further research is required to assess the long-term efficacy and safety of these drugs in children.

Acknowledgment: The authors wish to thank Miss Camille Petty, R.N., ward staff, teachers of P.S. 106, and Dr. Juanita Shell for their contribution, and Rowell Laboratories and McNeil Pharmaceutical for supplying the lithium, and placebo and haloperidol, respectively.

Monoamine Receptor Sensitivity and the Mechanism of Action of Antidepressant Treatment

Chair: George R. Heninger, M.D.
Department of Psychiatry
Yale University School of Medicine
New Haven, Connecticutt

The Monoamine Receptor Sensitivity Hypothesis of Antidepressant Drug Action[1]

George R. Heninger, M.D.,[2] and Dennis S. Charney, M.D.[2]

The generalized monoamine receptor sensitivity hypothesis of antidepressant drug action is based on the premise that the therapeutic action of antidepressant treatments (ADT) results from changes in the sensitivity of several monoamine receptors. The overall net effect of these changes is to increase neurotransmission in several monoamine systems. This hypothesis was stimulated by the findings that the electrophysiological sensitivity of single cells to both norepinephrine (NE) and serotonin (5-HT) was increased following long-term antidepressant treatment (Aghajanian 1981), and it is based on the review of a large number of recent studies which have elucidated many of the complex effects of long-term antidepressant treatment (ADT) on monoamine receptor function (Charney et al. 1981a). Similar earlier hypotheses have usually focused on only one monoamine system (Sulser et al. 1978).

The original monoamine deficiency hypothesis of depression (Schildkraut 1965; Bunney & Davis 1965) and its more recent modifications (Maas 1975) were based on the premise that the therapeutic action of drugs is the consequence of an increased availability of synaptic norepinephrine (NE) or serotonin (5- HT) secondary to high affinity reuptake inhibition and/or decreased catabolism. This hypothesis has been questioned on two grounds: a) Some clinically effective antidepressant drugs, such as iprindole and mianserin do not inhibit amine uptake or metabolism (Gluckman & Baum 1969; Goodlet, et al. 1977), and some reuptake inhibitors, such as amphetamine, femoxetine, or cocaine are not effective antidepressant treatments (Overall et al. 1962; Post et al. 1974; Ghose et al. 1977). b) There is an obvious temporal discrepancy between the rapid drug-induced biochemical effects on amine uptake and catabolism, which occur within hours, and the clinical antidepressant response which occurs only after 7-14 days of treatment (Oswald et al. 1972). In addition, studies of NE and 5-HT turnover in animals

following long-term ADT treatment show no consistent changes across the wide spectrum of antidepressant compounds or ECT (Charney et al. 1981a).

Since changes in amine uptake or catabolism do not easily explain the effects of long-term ADT on the behavior of animals or patients, current research has focused on the effects of ADT on monoamine receptor function. Major advances elucidating the complex effects of long-term ADT on NE, dopamine (DA), 5-HT, and histamine (H) receptor function have been facilitated by new developments in radioligand receptor binding, single unit electrophysiological recordings, pharmacologic characterization of cyclic adenosine 3′5′ monophosphate (cAMP) production, and neurotransmitter behavioral paradigms. All of these methods are capable of assessing receptor regulation and function, and they have led to an improved understanding of the effects of long-term ADT.

Receptor Sensitivity in Animals on Long-Term Antidepressant Treatment

Table 1 presents a general summary of the effects of long-term ADT on measures of monoamine receptor sensitivity measured by biochemical, physiologic, and behavioral methods across the receptors for these four monoamine neurotransmitters. (*See* Charney et al. 1981a for a detailed review of this area.) Following long-term ADT there is a decrease in beta receptor binding and a decrease in beta receptor stimulated increase of cAMP. Physiologic studies have, in general, tended to confirm this, but behavioral models for assessing beta receptors are not available.

Long-term ADT produces an increase in alpha-1 receptor sensitivity as indicated by electrophysiologic and behavioral measures. In contrast, no consistent changes in alpha-1 receptor binding have been observed. Alpha-2 sensitivity is decreased or unchanged depending on the drugs studied and the paradigm used. However, changes in alpha-2 sensitivity may reflect an important mechanism of action of some antidepressant drugs, and further studies are necessary to fully evaluate this possibility.

In the dopaminergic system, receptor binding studies demonstrate no change or possibly an increased binding assumed to occur on post synaptic receptors. Electrophysiologic and behavioral studies of the DA system demonstrate presynaptic subsensitivity and a postsynaptic supersensitivity. Thus, chronic ADT treatment appears to augment overall transmission in the dopaminergic system.

Table 1

Effects of Long-Term Antidepressant Treatment on Monoamine Receptor Sensitivity

Monoamine Receptor Type	Measures of Monoamine Receptor Sensitivity		
	Receptor Binding or cAMP Production	Sinble Unit Electrophysiology	Behavioral
Noradrenergic			
Beta	↓	0↓	—
Alpha 1	0	↑	↑
Alpha 2	↓↑	0↓	0↓
Dopaminergic			
Presynaptic	—	↓	↓
Postsynaptic	0↑	—	↑
Serotonergic	0↓	↑	↑
Histaminergic	0	↑	—

↑ = increase, ↓ = decrease, 0 = no change, — = not tested

Receptor binding in the serotonergic system has generally been found to be decreased, although it was increased following ECT. The increase in serotonergic receptor sensitivity assessed with electrophysiologic measures is consistent with the behavioral studies demonstrating increased sensitivity in this system.

A recent study in the histaminergic system has shown that changes in the sensitivity for cAMP production are not altered by chronic ADT, but that physiologic sensitivity is increased (Olianas et al. 1981). To date, histaminergic behavioral responses have not been studied following chronic ADT.

A careful examination of the studies mentioned above indicates that, particularly in the case of the alpha-1 and serotonin receptor systems, there is either no correlation or an inverse correlation between changes in receptor number determined by ligand binding and functional sensitivity assessed by electrophysiologic or behavioral techniques. It should be emphasized that changes in receptor number represent only one of several ways that sensitivity to a hormone or neurotransmitter may be regulated. It is possible that the sensitization of NE or 5-HT responses could result from antidepressant-induced changes in the coupling of alpha-adrenergic or 5-HT receptors to effector mechanisms or to changes in the effector mechanism itself. In this regard it is important to note that whereas antidepressant treatment has been shown to increase behavioral alpha-1 adrenergic sensitivity in the spinal cord without any increase in alpha-1 receptor binding, denervation with 6-hydroxydopamine does cause both increased alpha-1 sensitivity and alpha-1 binding (Davis et al. 1981).

A summary of the animal studies indicates that following long-term ADTs there is reduced beta adrenergic sensitivity while overall responsivity to alpha-1 adrenergic, postsynaptic, dopaminergic, serotonergic, and histaminergic stimulation appears to be increased. These changes in sensitivity occur with a time course that is similar to the 7- to 14-day delay in ADT effects observed in patients. Receptor sensitivity changes have usually been shown to occur following long-term administration of all effective antidepressive treatments (i.e., tricyclic antidepressants, 'atypical drugs,' monoamine oxidase inhibitors, and ECT). Thus, the receptor changes are observed irrespective of the markedly divergent pharmacologic profiles of the ADTs that induce them.

Receptor Sensitivity in Patients and Effects of Antidepressant Treatment

In rats, invasive procedures and pharmacologic experiments are conducted to verify that the neurotransmitter agonists and antagonists are indeed affecting the neurotransmitter system under study. Since this is not possible in humans, an alternative strategy has been utilized where a clinically safe neurotransmitter agonist or antagonist is administered. The changes in biochemical and physiological measures produced by the action of the agonist or antagonist on the putative receptor are used as a measure of that receptor's sensitivity. Using this paradigm, human studies have been conducted which support the hypothesis that changes in receptor sensitivity are relevant to the treatment of depressed patients.

A summary of the findings on noradrenergic receptor sensitivity in depressed patients is presented in Table 2. The alpha-2 agonist, clonidine, has been utilized to test the sensitivity of the presynaptic alpha-2 receptor. The dependent measures have been plasma MHPG and blood pressure (BP), both of which are reduced secondary to stimulation of brain alpha-2 adrenergic receptors. As can be seen in Table 2, the effect of clonidine on plasma MHPG and BP is not abnormal in depression (Charney et al. 1982). Treatment with desipramine produced a subsensitivity to clonidine, as measured by both plasma MHPG and BP (Charney et al. 1981b).

Table 2

Noradrenergic Receptor Sensitivity in Depressed Patients

Location	Type	Stimulus	Variable Measured	Level of Sensitivity (Patients vs. Controls)
Presynaptic	α_2	clonidine	plasma MHPG	normal
		clonidine	blood pressure	normal
Postsynaptic	α_2	clonidine	growth hormone	decreased
	α?	amphetamine	corticosteroid	decreased
	α?	dexamethasone	cortisol	decreased
	β	light	melatonin	decreased

Clonidine has been postulated to release growth hormone (GH) via direct action on adrenergic postsynaptic receptors. In depressed patients the GH response to clonidine is decreased (Matussek et al. 1980; Checkley et al. 1981; Charney et al. 1982). At present, it does not appear that this subsensitivity to clonidine is normalized following effective antidepressive treatment (Charney & Heninger 1982). However, there is still the possibility that this test will normalize when patients recover from their illness, i.e., when they can remain symptom-free off medication. Depressed patients have been found to have an impaired release of corticosteroids following stimulation by methylamphetamine. This response was normalized when patients were recovered and retested off medication (Checkley 1979). The resistance of plasma cortisol to dexamethasone suppression occurs in approximately 50 percent of patients and has been found to normalize with effective clinical treatment (Greden et al. 1980). The neurotransmitter receptors involved in the Dexamethasone Suppression Test have not been clearly established, although there is some evidence that an abnormal test could reflect subsensitive alpha adrenergic receptors.

The biochemical and neurophysiologic studies indicate that beta adrenergic receptors are decreased in sensitivity following chronic antidepressant treatment. No animal behavioral model has been found to adequately test the sensitivity of this receptor. It is of some interest that manic depressive patients have an increased sensitivity to light when plasma melatonin has been assayed (Lewy et al. 1981). Melatonin production is inhibited by light and increased by stimulation of beta receptors on the pineal. If the sensitivity of the other synapses in the neural chain between the retina and the superior cervical ganglia is unchanged and if the sensitivity of the beta receptor on the pineal is increased, the effects of light would not reduce melatonin secretion so readily. Thus, this very preliminary data would suggest that in manic depressive patients the sensitivity of the beta adrenergic system on the pineal is decreased. A decrease in beta receptor sensitivity following ADT would obviously not correct an abnormality in depression if beta receptors were already decreased before ADT was started.

Paradigms assessing central 5-HT receptors have not been well developed. The prolactin response following thyrotropin releasing hormone appears to be mediated by a central 5-HT mechanism. This response was potentiated in patients treated with ECT, which is consistent with the animal studies mentioned above (Coppen et al. 1980). Currently, there is considerable research activity in this area and data from additional studies should soon be available (Charney & Heninger 1982).

Discussion

The generalized monoamine receptor sensitivity hypothesis of antidepressant drug action is supported by three lines of evidence:

1. In animals long-term ADT produces changes in receptor sensitivity of at least four monoamine systems, i.e., decreased sensitivity at NE beta and increased sensitivity at NE alpha-1, DA, 5-HT, and H postsynaptic receptors with little evidence of change in acetylcholine, GABA, or glutamate sensitivity.
2. Similar changes in monoamine receptor sensitivity are seen following long-term treatment with very dissimilar drugs, i.e., drugs with very different pharmacologic profiles appear to have a common mechanism of action after long-term administration.
3. The changes in monoamine receptor sensitivity only occur following longer term administration, i.e., 7-14 days, a time course which is consistent with the delayed therapeutic effects of these treatments.

The eventual proof of this hypothesis must await clinical confirmation since the therapeutic mechanisms of action in depressed humans could be quite different than those seen in healthy young rats given larger relative doses of drug treatments. Therefore, it is important that clinical researchers be able to take advantage of the increasing number of methods available for evaluating this hypothesis in patients.

The data from studies of long-term ADTs on receptor sensitivity indicate that the original monoamine deficiency hypothesis requires modification and expansion. The enhancement of sensitivity by ADT of alpha adrenergic and serotonergic postsynaptic receptors is consistent with the original hypothesis that depressed patients have subnormal NE and/or 5-HT functional activity. Thus, the discovery of atypical agents, such as iprindol or mianserin, which were originally thought to weaken this hypothesis, may actually support it if the chronic effects of these agents on monoamine receptor sensitivity are taken into account. As mentioned, the induction of beta-adrenoceptor subsensitivity by ADT has prompted proposals (tantamount to a reversal of the monoamine deficiency hypothesis) that depression is the result of increased noradrenergic activity, at least in the beta noradrenergic system (Sulser et al. 1978). The opposite effects of long-term ADT on alpha and beta receptors do not necessarily have to be interpreted as incompatible. The reciprocal regulation of these adrenergic receptors observed in many studies may be an important mechanism for the homeostatic control of central noradrenergic activity. Thus, the effects induced by chronic antidepressant treatment on the relative sensitivity of alpha and beta adrenoceptors may serve to correct a disorder of adrenergic regulation in affective illness, where the balance between alpha and beta receptor sensitivity is more important than just the absolute effect in either system.

One of the most fundamental and far-reaching implications of the receptor sensitivity hypothesis is the opportunity that it allows for study of the mechanism of action of ADTs at the molecular level. If the induction of increased monoamine receptor sensitivity is an important common mechanism of action of ADTs, then the molecular mechanisms involved in the genesis of this process should allow for the development of much more specific, definitive, and efficacious treatments.

Summary

The generalized monoamine receptor sensitivity hypothesis of antidepressant drug action is based on the evidence that all ADTs produce changes in monoamine receptor sensitivity and that the time course of these changes is similar to the delayed therapeutic actions of these treatments. Long-term ADT has been found to reduce beta-adrenergic sensitivity while enhancing responses to alpha-adrenergic, dopaminergic, serotonergic, and histaminergic stimulation. The initial data from clinical studies suggest that postsynaptic adrenergic alpha receptors may be subsensitive in depression. This would support the hypothesis that depression is a result of decreased monoamine receptor sensitivity and that effective antidepressant treatment may reverse this abnormality.

Acknowledgment: Appreciation is extended to Grace M. Billings and Stella Rek for excellent secretarial help.

Catecholamine-Stimulated Production of Melatonin After Administration of Antidepressants

William E. Heydorn,[1] Stanley Caroff, M.D.,[2] and Alan Frazer, Ph.D.[3]

It is now established that repeated treatment with antidepressant drugs produces effects different from those observed after their acute administration. For example, repeated, but not acute, administration of either the tricyclic antidepressants or the monoamine oxidase inhibitors produces a decrease in the number of β-adrenergic receptors and a reduced ability to generate adenosine 3′, 5′-monophosphate (cyclic AMP) in response to catecholamine (*see* Frazer 1981a,b). What remains unclear is whether such effects have any impact on the overall response of the tissue to catecholamine. To assess this, we examined the effect of repeated administration of antidepressant drugs to rats on catecholamine-elicited production of N-acetyl-5-methoxytryptamine (melatonin) by the pineal gland. The pineal gland contains a high density of β-adrenergic receptors (Greenberg & Weiss 1979) coupled to a catecholamine-sensitive adenylate cyclase receptor that generates cyclic AMP (Weiss & Costa 1968). The β-adrenergic receptors of the pineal gland are activated either pharmacologically by exogenous administration of catecholamine or physiologically by the onset of darkness. Darkness, acting through a multisynaptic pathway, causes the release of norepinephrine from sympathetic nerve terminals innervating the pineal gland (Brownstein & Axelrod 1974). The resultant increase in the glandular content of cyclic AMP (Heydorn et al. 1980) initiates a cascade of processes resulting in the production of melatonin (*see* Klein 1979). Thus, melatonin levels are indicative of the activity of the β-adrenergic receptor/adenylate cyclase/cyclic AMP complex of the pineal gland.

[3] Departments of Pharmacology and Psychiatry, University of Pennsylvania and Veterans Adminstration Hospital, Philadelphia, PA 19104.

Male Sprague-Dawley rats, housed on a 12-hour light/dark cycle (lights on at 0700 hr), were used in these experiments. Animals received intraperitoneal injections of the tricyclic antidepressant desmethylimipramine (DMI) (10 mg/kg), or the monoamine oxidase inhibitor nialamide (40 mg/kg), either acutely or twice daily for 7 days. Control animals received 0.9 percent NaCl. Rats treated repeatedly were killed 24 hours after the last injection. It was found that such treatments reduced the number of β-adrenergic receptors of the pineal gland at this time. Rats treated acutely were decapitated 5 hours after drug adminstration.

The first series of experiments examined the effect of repeated antidepressant administration on the melatonin concentration of pineal gland and serum over a 24-hour cycle. Rats were treated as described above and killed at 1000, 1600, 2200, 2400, 0200, 0400, or 0600 hours. Pineal glands and serum were collected and, after extraction with chloroform and washing with petroleum ether, assayed for melatonin by a radioimmunoassay procedure (Pang et al. 1977). The data obtained were analyzed by analysis of variance and Duncan's Multiple Range Test.

The onset of darkness caused a marked elevation of the melatonin concentration in both pineal gland and serum of control rats. Pineal gland melatonin levels rose from approximately 200 picograms/gland during the day to a peak of 4000 picograms/gland at night. Serum melatonin values also rose significantly, from a daytime concentration of 7 picograms/ml to a nighttime level of 45 picograms/ml. Repeated treatment of rats with DMI produced a significant decrease in the nighttime rise of melatonin in both the pineal gland ($p<0.05$) and in serum ($p<0.01$). Similar results were obtained when rats were treated repeatedly with nialamide (pineal gland, $p<0.01$; serum, $p<0.05$). The extent of the inhibition of the nighttime rise of melatonin produced by repeated administration of these antidepressant drugs was about 25 percent. By contrast, if either DMI or nialamide were administered acutely at 1900 hours and the rats killed at midnight, there was no difference in pineal gland or serum melatonin levels in drug-treated rats as compared to that measured in control animals.

In a second series of experiments, melatonin production in the pineal gland was stimulated pharmacologically by the subcutaneous administration of L-isoproterenol. Rats were treated repeatedly with DMI, nialamide, or 0.9 percent NaCl as described above and then, 21 hours after the last injection, were administered either 0.5 mg/kg or 1 mg/kg L-isoproterenol. Three hours later the rats were killed and the pineal glands removed and assayed for melatonin. In control rats, administration of L-isoproterenol caused a marked elevation of pineal gland melatonin concentrations above baseline, about 15-fold with the lower dose of the catecholamine and about 20-fold with the higher dose. Repeated administration of DMI reduced significantly (by about 50%) the ability of either dose of L-isoproterenol to increase melatonin concentrations in the pineal gland ($p<0.01$). Similar results were seen upon repeated administration of nialamide to rats. However, if rats were treated acutely with either DMI or nialamide, the stimulatory effect of L-isoproterenol on melatonin levels in the pineal gland was essentially identical to that seen in control animals.

Therefore, in the pineal gland it appears that antidepressant drug-induced subsensitivity of β-adrenergic receptors with concomitant reduced responsiveness of the adenylate cyclase/cyclic AMP system results in a significant decrease in the ability of catecholamines to raise the concentration of melatonin in the gland.

Since this inhibitory effect of melatonin production after repeated antidepressant administration was detected in serum, we wanted to examine whether depressed patients treated with DMI would also show a blunted nighttime rise of melatonin while treated with the tricyclic drug. To date, one patient has been studied. This male unipolar depressed inpatient, aged 34, had a good clinical response to DMI, as shown by Hamilton Depression Scale scores decreasing from 22 prior to treatment to 6 after 4 weeks of treatment. Serum was obtained for melatonin analysis every 1.5 hours between 1730-0600 hours, with lights turned off at 2200 hours. This was done prior to treatment and after 4 weeks of treatment with DMI. Prior to treatment, the patient showed markedly elevated serum concentrations of melatonin during the night (about 115 pg/ml) as compared to those measured in the daytime (about 30 pg/ml). After treatment with DMI, the serum concentration of melatonin rose shortly after the lights were turned off, but then fell during the course of the night. As a consequence, while the patient was treated with DMI the mean nighttime concentration of melatonin in the serum of this patient (58 ± 11 pg/ml; average of the five values taken between midnight and 6:00 am) was significantly lower than those measured over the corresponding times prior to treatment (114 ± 9 pg/ml; $p<0.005$). Such data are consistent with the belief that antidepressant treatments produce β-adrenergic receptor subsensitivity in patients, although other interpretations of the data are possible also. Further work will be needed to determine whether this approach can provide an index of β-adrenergic subsensitivity in patients. If it can, then the possible clinical importance of the β-receptor subsensitivity produced by antidepressant treatments can be evaluated.

Agonist-Induced Changes in Behavior as a Measure of Functional Changes in Receptor Sensitivity Following Chronic Antidepressant Treatments[1]

Michael Davis, Ph.D.[2]

Introduction

Therapeutic effects of antidepressant drugs typically do not appear until 2 or more weeks after treatment initiation (Oswald et al. 1972; Klein et al. 1980). Hence, the neuropharmacological actions of antidepressant treatments that accompany chronic as opposed to acute administration should be the ones most relevant to their therapeutic effects. In recognition of this, an increasing number of biochemical and electrophysiological studies are being done to determine changes in neural transmission following chronic antidepressant treatments. However, as elegant as these studies might be, it is important to emphasize that changes in behavior ultimately have to be used to determine functional changes in neural transmission. In general, two broad classes of behavior could be brought to bear on this question. One would include "animal models of depression" in which the behavior of the animal bears some resemblance to human depression. Paradigms such as learned helplessness, the swimming despair test, or social behavior of nonhuman primates following early isolation would be examples. Paradigms such as these have already proved to be important for screening prospective antidepressant drugs and ultimately will be very important for analyzing the etiology of depression. At the present time, however, the complexity of these paradigms makes them difficult to use as behavioral tests to deduce changes in specific transmitter systems following antidepressant treatments.

Behavioral tests of the second class are ones that have been shown to be modulated by specific central neurotransmitter systems judged by their response to selective pharmacological agonists. These tests are not used as model systems of depression, but as model behavioral systems for deducing functional changes in specific neurotransmitter systems. For example, it is well documented that the drug apomorphine elicits stereotyped behavior via activation of dopamine systems in the brain. Thus, changes in the ability of apomorphine to elicit stereotyped behavior following antidepressant treatments can be used to infer how antidepressants alter functional dopamine transmission.

In the present paper, experiments will be reviewed that use changes in behavioral output induced by selective agonists to assess functional changes in receptor sensitivity following chronic as compared to acute antidepressant treatments. Recent studies in the author's own laboratory will then be reviewed which show that the acoustic startle reflex may be an especially good test system to analyze functional changes in different neurotransmitter systems. Finally, changes in alpha-1 and alpha-2 adrenergic receptor sensitivity following chronic vs. acute treatment with selected tricyclic antidepressant drugs using acoustic startle will be presented.

Table 1

Functional Changes in Dopamine Transmission Based on Behavioral Measures

Treatment	Treatment Test Interval	Probe Drug	Behavior	Treatment Effect	Authors
ECS (× 10)	24 hrs	Methamphetamine	Activity Increase	Enhance	Green et al. 1977
ECS (× 10)	24 hrs	Tranylcypromine L-DOPA	Activity Increase	Enhance	Green et al. 1977

Functional Changes in Receptor Sensitivity Following Antidepressant Treatments

Table 1 summarizes studies that have assessed functional changes in dopamine (DA) transmission following chronic antidepressant treatments. In this and all subsequent tables, only studies in which chronic treatments have been used will be included. In general, the effects to be reported only occur after chronic and not acute treatment, although this comparison has not been included in every study.

Table 1 shows that chronic antidepressant treatments tend to enhance DA transmission when behavioral testing occurs at least 24 hours after the final treatment. Repeated applications of electroconvulsive shocks (ECS) enhance the ability of DA agonists such as amphetamine, L-DOPA, or apomorphine to increase locomotor activity (Green et al. 1977; Green & Deakin 1980) or of apomorphine to increase turning in 6-OHDA lesioned rats (Green et al. 1977); or to produce stereotyped behavior (Serra et al. 1981). Repeated ECS or chronic treatment with different antidepressant drugs blunts the ability of low doses of apomorphine to depress locomotor activity, suggesting a net increase in DA transmission (Serra et al. 1979, 1981). Three ECS treatments

Table 2

Functional Changes in Serotonin Transmission Based on Behavioral Measures

Treatment	Treatment Test Interval	Probe Drug	Behavior	Treatment Effect	Authors
ECS (× 10)	24-72 hrs	Tranylcypromine + L-tryptophan	Activity	Enhance	Green et al. 1977 Costain et al. 1979
ECS (× 10)	24 hrs	5-MeODMT	Activity	Enhance	Evans et al. 1976

improve the ability of rats to discriminate amphetamine or apomorphine from saline in a drug discrimination paradigm (White & Barrett 1981). Finally, 2 weeks' administration of desipramine increased rates of intracranial brain stimulation in areas of the midbrain that contain DA cells (Fibiger & Phillips 1981). The results of the last two studies would again point to an enhancement of DA transmission. On the other hand, Table 1 also shows that when testing occurs shortly after the last injection of an antidepressant drug, no increase in apomorphine's effect can be demonstrated (Maj et al. 1979b; Delini-Stula & Vassout 1979).

Table 2 shows that chronic antidepressant treatments also increase functional serotonin (5-HT) transmission, provided that testing occurs at least 12-24 hours after the last treatment. Repeated ECS enhances the ability of various 5-HT agonists to increase locomotor activity (Green et al. 1977, 1980; Costain et al. 1979; Evans et al. 1976) or behaviors associated with heightened 5-HT transmission such as head twitches (Lebrecht & Nowack 1980). Repeated administration of different antidepressant drugs also enhances the ability of 5-HT agonists to increase head twitches (Friedman & Dallob 1971; Fuxe et al. 1981), wet dog shakes (Moglinicka & Klimek 1979) or sleep time in young chicks (Jones 1980), although in some cases this enhancement may only occur with certain doses of 5-HT agonists with reversed effects at other doses (Fuxe et al. 1981). Again, the interval between testing and the last antidepressant treatment is critical, since comparable increases in the effects of 5-HT agonists are not seen at short intervals (Lebrecht & Nowack 1980; Friedman & Dallob 1979; Huang & VanWoert 1980).

Table 3 suggests that chronic antidepressant treatments may increase functional alpha-1 adrenergic transmission. However, the data here are less clear, since the pharmacological mechanisms underlying changes in these behaviors induced by the drugs that were used is

Table 3

Functional Changes in α_1-Adrenergic Transmission Based on Behavioral Studies

Treatment	Treatment Test Interval	Probe Drug	Behavior	Treatment Effect	Authors
Imipramine Amitriptyline Danitracen × 10	24-72 hrs	High-Dose Clonidine	Activity	Increase Activity in TCA-Treated Animals	Maj et al. 1979a
Amitriptyline Imipramine Desipramine Clomipramine Mianserin Danitracen Iprindole × 14	2 hrs	High-Dose Apomorphine	Aggression	Enhance	Maj et al. 1979b
Imipramine Mianserin Iprindole × 10	2 hrs	Very High-Dose Clonidine	Aggression	Enhance	Maj et al. 1980
ECS ×7	24 hrs	Reserpine + Apomorphine + Clonidine+	Activity	Enhance	Modigh 1975
Imipramine Amitryptyline ×21	20 hrs	Yohimbine or Clonidine	Cessation of Swimming in "Despair Test"	Yohimbine Potentiates Effects of TCAs Clonidine Blocks Effects of TCAs	Zebrowska-Lupina 1980

not well documented. Chronic antidepressant drugs or ECS increase the ability of high doses of clonidine to increase locomotor activity alone (Maj et al. 1979a) or in combination with reserpine plus apomorphine (Modigh 1975). Antidepressants also increase apomorphine or clonidine-induced aggression, which can be blocked by the alpha-1 antagonist phenoxybenzamine (Maj et al. 1979b, 1980). Clearly, these data are only suggestive for an enhancement of alpha-1 adrenergic transmission, but they assume greater interest in view of other findings. First, Tables 1 and 2 indicate that the enhancement by ECS of the ability of either DA or 5-HT agonists to increase locomotor activity can be blocked by prior norepinephrine (NE) depletion via administration of 6-OHDA (Green & Deakin 1980). Second, Table 3 shows that the therapeutic effect of chronic imipramine or amitriptyline in the swimming despair test is potentiated by the drug yohimbine and blocked by the drug clonidine (Zebrowska-Lupina 1980). Since these drugs increase and decrease NE transmission, respectively, the data support a role for NE in mediating the effects of these tricyclic antidepressant compounds in this test.

Finally, Table 4 indicates that chronic treatment with desipramine blunts the ability of a low dose of clonidine to decrease locomotor activity when testing occurs 48 hours after the last antidepressant treatment (Spyraki & Fibiger 1980) but not when testing occurs shortly after 7 days of imipramine (VonVoightlander et al. 1980). These data suggest that chronic desipramine may decrease functional sensitivity of alpha-2 receptors, although it is not known if this would occur if other antidepressant treatments were used as well.

Table 4

Functional Changes in α_2-Adrenergic Transmission Based on Behavioral Measures

Treatment	Treatment Test Interval	Probe Drug	Behavior	Treatment Effect	Authors
Desipramine × 15	48 hrs	Low-Dose Clonidine	Activity Decrease	Blunt	Spyraki & Fibiger 1980
Imipramine × 7	3.5 hrs	Clonidine	Activity Decrease	No Change	Von Voightlander et al. 1978

Table 5

Acoustic Startle as a Behavioral Test for Analyzing Functional Changes in Receptor Sensitivity Following Agonist Challenge

Receptor System	Agonist	Route	Dose Range	Effect on Startle
Norepinephrine				
Alpha-1	Phenylephrine	Intrathecal	6-50 μg	Increase
Alpha-2	Clonidine	Intraperitoneal	10-40 μg/kg	Decrease
Serotonin				
Forebrain-Inhibitory	Serotonin	Intraventricular	3-50 μg	Decrease
Spinal-Excitatory	Serotonin	Intrathecal	12-100 μg	Increase
	5-MeODMT	Intraperitoneal	0.5-4 mg/kg	Increase
Dopamine	Apomorphine	Intraperitoneal	0.2-3 mg/kg	Increase

Acoustic Startle as a Behavioral Test for Analyzing Functional Changes in Receptor Sensitivity Following Agonist Challenge

Over the last several years our laboratory has been investigating how various neurotransmitter systems modulate the acoustic startle reflex. Acoustic startle is a brainstem reflex that has a latency of only 8 msec in the rat measured electromyographically. Startle is sensitive to a variety of environmental variables and shows habituation, sensitization, pre-pulse inhibition, and modification by prior classical conditioning (cf., Davis 1980). Recently it has been determined that the neural circuit that mediates startle may consist of the ventral cochlear nucleus, the dorsal and ventral nuclei of the lateral lemniscus, a ventral region of the pontine reticular formation, and lower motor neurons in the spinal cord (Davis et al., in press). The simplicity of the reflex allows one to determine, therefore, where in the central nervous system various neurotransmitters might act in its modulation.

Table 5 summarizes specific data to indicate that startle could be used as a single test system to analyze changes in the sensitivity of NE, 5-HT, and DA systems following antidepressant treatments. Startle is increased via stimulation of alpha-1 receptors in the spinal cord. Thus, direct infusion of NE itself or the alpha-1 agonist phenylephrine into the subarachnoid space (intrathecal administration) increases acoustic startle. This effect is blocked by the alpha-1 antagonist WB-4101, but not by the 5-HT antagonist cyproheptadine or the DA antagonist haloperidol or the beta-adrenergic antagonist propranolol (Astrachan & Davis 1981). Moreover, the phenylephrine effect can be enhanced by prior selective depletion of spinal NE following intrathecal administration of 6-OHDA (Astrachan, Davis, and Gallager, in preparation).

In contrast, acoustic startle is markedly depressed by the alpha-2 adrenergic agonist clonidine (Davis et al. 1977). This effect can be blocked by the alpha-2 antagonists piperoxane or yohimbine (Davis et al. 1977; Davis & Astrachan 1981).

Serotonin has opposite effects on startle depending on whether it acts in the forebrain or spinal cord. Direct infusion of 5-HT itself or 5-HT agonists intraventricularly depresses startle (Davis et al. 1980b; Commissaris & Davis 1982). On the other hand, direct infusion of 5-HT or 5-HT agonists into the spinal subarachnoid space increases acoustic startle (Davis et al. 1980a, b).

Finally, startle is increased by DA, since systemic administration of the DA agonists apomorphine or *d*-amphetamine increases acoustic startle (Davis & Aghajanian 1976; Davis et al. 1977). These effects can be blocked by the DA antagonists haloperidol or pimozide (Davis & Aghajanian 1976; Kehne & Sorenson 1978).

Changes in Functional Alpha-1 and Alpha-2 Adrenergic Receptor Sensitivity Following Tricyclic Antidepressant Drugs

Studies are now underway to use startle as a test system to determine changes in functional receptor sensitivity following antidepressant treatments. Thus far the work has focused on changes in functional NE transmission, since other behavioral data suggest that such effects on NE might interact with changes in 5-HT and DA transmission following chronic antidepressant treatments, as well as being important by themselves.

Changes in Alpha-2 Sensitivity

In the first experiment the effects of three tricyclic antidepressant (TCA) drugs on functional changes in alpha-2 adrenergic transmission were assessed by measuring the degree to which clonidine would depress startle following chronic treatment with antidepressants or saline (Davis & Menkes, in press). Four groups of 20 rats each were used. Animals in each group were injected intraperitoneally (i.p.) once a day for 14 days with saline, desipramine HCl (DMI, 10 mg/kg, USV Pharmaceuticals), amitriptyline (AMI, 10 mg/kg, Merck Sharpe and Dohme), or iprindole (IPR, 5 mg/kg, Wyeth Labs). All drug weights are based on the weight of the salt. Twenty-four hours after the last injection five rats in each group were injected with saline and five with clonidine (20 µg/kg). Immediately afterward they were placed into the startle test cages described elsewhere

(Davis et al. 1980b) and presented with a total of 90 noise bursts (110 db) at a 20-second interburst interval, creating a 30-minute test session. Twenty-four hours later the same procedure was repeated except rats previously given saline were now given clonidine (20 μg/kg) and vice versa. The other rats in each of the groups were tested identically with the exception that the dose of clonidine was 40 μg/kg.

To determine if any of the tricyclics might alter the effect of clonidine on startle after acute administration, an additional 4 groups of 10 rats each were given saline, 10 mg/kg DMI, 10 mg/kg AMI, or 5 mg/kg IPR. One hour later, half the rats in each group were injected with saline and half with clonidine (40 μg/kg) and then tested for startle over the next 30 minutes as described earlier. Twenty-four hours later the same tricyclic treatments were repeated, and 1 hour later the rats were given clonidine or saline. In this case, however, rats previously given clonidine were given saline and vice versa.

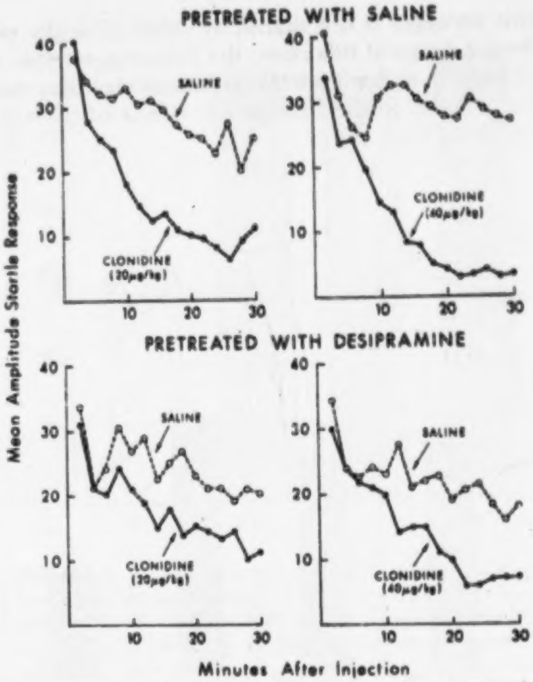

FIGURE 1. Mean amplitude startle response at various times after injection of saline or 20 or 40 μg/kg clonidine in rats pretreated for 14 days with either saline (top) or 10 mg/kg desipramine (bottom).

Figure 1 illustrates that chronic DMI treatment attenuated the depressant effect of either 20 or 40 μg/kg clonidine on acoustic startle. Thus, in the saline-treated rats, clonidine markedly depressed startle within about 10 minutes after injection after either 20 or 40 μg/kg, $t = 7.09$, $p < .001$ and $t = 10.19$, $p < .001$, respectively. Clonidine also depressed startle in the rats treated chronically with DMI, $t = 4.27$, $p < .001$; $t = 6.83$, $p < .001$ for doses of 20 or 40 μg/kg, respectively. However, the magnitude of the depressant effect was less in the DMI-treated rats at both of the test doses of clonidine. For example, from 10 to 20 minutes after injection clonidine depressed startle in rats pretreated with saline by about 55 percent after 20 μg/kg and about 75 percent after 40 μg/kg. In contrast, the same doses of clonidine depressed startle by about 30 and 45 percent in the rats pretreated with DMI, and the difference in the magnitude of depression between saline and DMI pretreated rats was significant at each test dose of clonidine, $t = 2.79$, $p < .01$ for 20 μg/kg; $t = 3.29$, $p < .01$ for 40 μg/kg. The attenuated response to clonidine after DMI occurred in both replications and was significant in each case.

On the other hand, chronic treatment with either AMI or IPR did not alter the depressant effect of clonidine on acoustic startle (Figure 2). After these tricyclics, the percentage changes in startle after either 20 or 40 μg/kg of clonidine were essentially identical to that after saline and significantly greater than the percent changes after DMI ($p < .01$ at each dose when DMI was compared with AMI or DMI was compared with IPR). Finally, none of the tricyclics significantly altered baseline startle levels after chronic administration.

In contrast to chronic DMI treatment, acute treatment with DMI or the other tricyclics did not significantly affect the response to 40 μg/kg clonidine relative to that observed after acute saline (percentage decreases = 80.0, 94.3, 88.9, and 77.4 after IPR, AMI, DMI, or SAL, respectively). Finally, none of the tricyclics significantly altered baseline startle levels at these doses (baseline means = 32.4, 29.8, 30.7, or 32.4 for IPR, AMI, DMI, and SAL, respectively).

These results indicate that chronic but not acute treatment with DMI attenuates the depressant effect of clonidine on acoustic startle. Since this property is not shared by other clinically effective drugs of this class, the data suggest that a change in alpha-2 adrenergic sensitivity may not be relevant to the therapeutic effects of tricyclic antidepressant drugs.

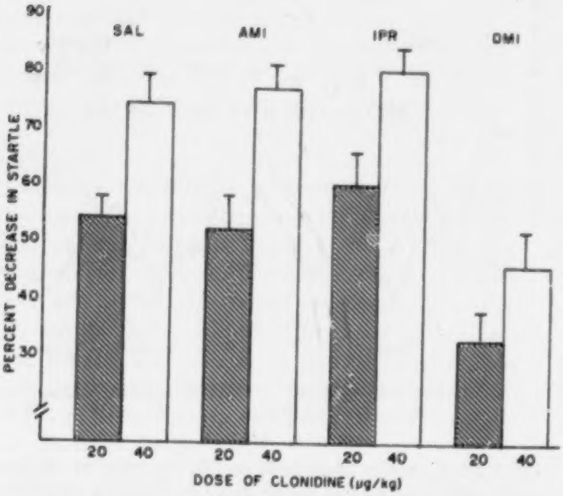

FIGURE 2. Percent decrease in startle after injection of either 20 or 40 µg/kg clonidine in rats pretreated for 14 days with either saline, amitriptyline (10 mg/kg), iprindole (5 mg/kg), or desipramine (10 mg/kg). Baseline means were unchanged by the chronic treatments (29.6, 28.8, 33.0, and 23.9 for the chronic saline, AMI, IPR, and DMI groups, respectively. *f* = 0.24, N.S.).

The next experiment sought to determine how chronic administration of tricyclic antidepressant drugs would alter alpha-1 adrenergic transmission (Menkes, Kehne, Gallager, Aghajanian, & Davis, in preparation). The same rats used for the study on clonidine were placed back on their respective saline or tricyclic drugs for another 7 days. The rats were then implanted with intrathecal catheters (Davis et al. 1980b) and 1 day later tested for startle by presenting noise bursts once every 20 seconds for 15 minutes. Following this pre-test, the rats were removed from the test cages and infused intrathecally with 25 µg of the alpha-1 adrenergic agonist phenylephrine in a volume of 10 µl at a rate of about 5 µl/minute. The rats were than tested for startle over the next 30 minutes by presenting 90 noise bursts every 20 seconds.

Figure 3 shows the mean amplitude startle prior to and following the infusion of phenylephrine in rats treated chronically for 21 days with either saline or amitriptyline. At this dose, phenylephrine had only a slight excitatory effect in rats chronically treated with saline. However, the magnitude of this effect was considerably larger in rats chronically treated with amitriptyline ($t = 2.35$, $p < .05$). Figure 4 summarizes data obtained after chronic treatment with other drugs. Consistent with the desipramine results, amitriptyline and iprindole also enhanced the effect of phenylephrine. Other experiments showed that this enhanced response to phenylephrine did not occur when testing was carried out 1 hour after a single dose of the tricyclics, a time when brain levels of the tricyclics are known to be higher than 24 hours after a chronic sequence (Vetulani et al. 1976).

Taken together, these data suggest that chronic but not acute treatment with three clinically effective antidepressant drugs increased functional alpha-1 adrenergic transmission. To determine if the enhanced behavioral response to phenylephrine might reflect an increase in the number of alpha-1 adrenergic receptor sites, the

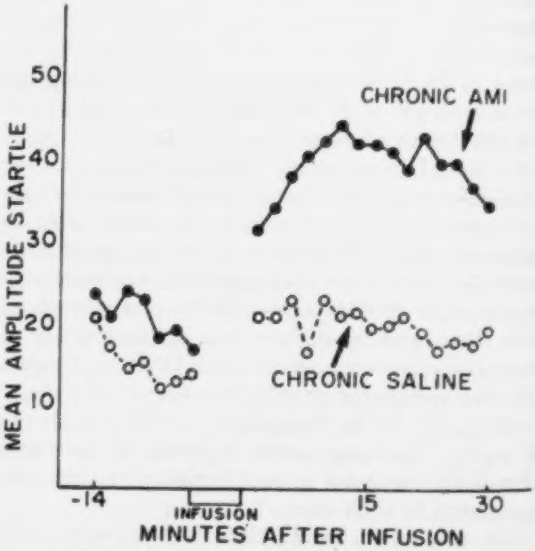

FIGURE 3. Change in startle amplitude before and after intrathecal administration of 25 µg phenylephrine in rats pretreated for 21 days with either saline or amitriptyline.

lumbar portions of the spinal cords from these rats were removed and prepared for 3H-prazosin binding according to the methods of Greengrass and Bremmer (1979). For comparison, rats pretreated 1 week earlier with intrathecal 6-OHDA were also included, since this treatment produces an enhancement of phenylephrine excitation or startle comparable in magnitude to that seen after 3 weeks' treatment of the antidepressant drugs. Figure 5 shows that prior 6-OHDA treatment increased the number of ^{3}H-prazosin binding sites, whereas pretreatment with the antidepressant drugs did not. Other experiments indicated that ^{3}H-prazosin also did not change in rats that were simply pretreated for 21 days with these same tricyclic compounds without getting the clonidine or phenylephrine tests on startle.

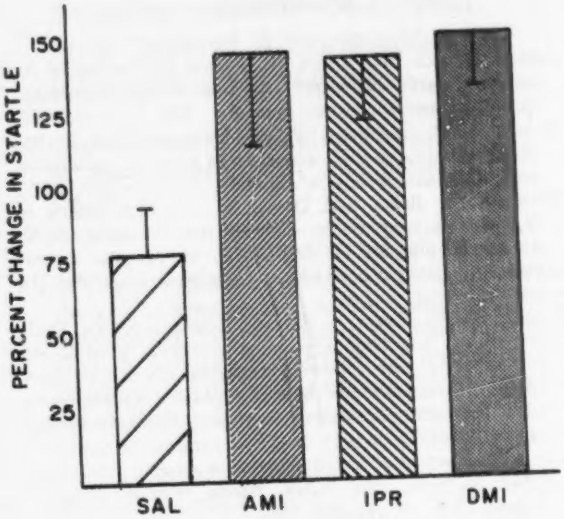

FIGURE 4. Percent change in startle from 0-30 min after intrathecal administration of 25 μg phenylephrine in rats pretreated for 21 days with either saline, amitriptyline (10 mg/kg), iprindole (5 mg/kg), or desipramine (10 mg/kg).

Discussion

To date, the available literature indicates that chronic compared to acute antidepressant treatments produce a pattern of functional changes in receptor sensitivity that includes an enhancement of central DA, 5-HT, and alpha-1 adrenergic sensitivity. These behavioral effects are consistent with enhanced electrophysiological responses to local application of 5-HT, NE, or DA in selected brain regions (cf., Charney et al. 1981). In contrast, changes in functional receptor sensitivity have not correlated with traditional receptor binding techniques, even when these have been done on parts of the nervous system that are known to mediate the behavioral effect (e.g., the present study). Future research should focus on mechanisms that might be common to 5-HT, DA, and NE at a level of neural transmission other than the receptor.

Acknowledgments: The work on chronic antidepressants was done in collaboration with Dr. Dorothy Gallager, John Kehne, and David Menkes. Our sincere thanks are extended to Lee Schlesinger for running the startle tests.

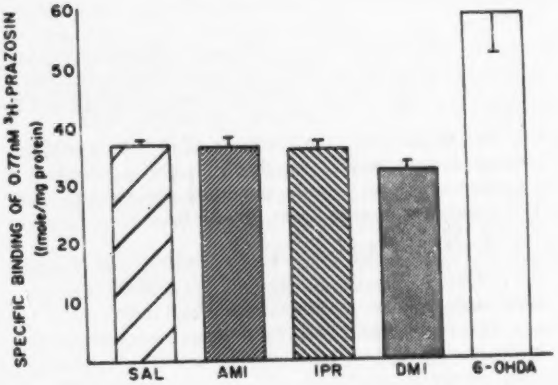

FIGURE 5. Specific binding of ^{3}H-prazosin (0.77 nM) to rat lumbar spinal cord membranes from rats tested for acoustic startle. Animals were killed 3 days after intrathecal injection of phenylephrine and 24 hours after their final chronic antidepressant or saline injection. Non-specific binding was determined by the addition of 1 μM WB-4101. Binding in individual animals was determined by quadruplicate determinations and each value plotted is the mean ± S.E.M. of at least eight treated animals.

Antidepressant Treatment and Central Adrenergic and Histamine Receptors

Ghanshyam N. Pandey, Ph.D.,[1] P. Sudershan, Ph.D.[1] and John M. Davis, M.D.[1]

The presumed mode of action of antidepressant drugs has been related to their ability to increase postsynaptic concentrations of neurotransmitters such as norepinephrine (NE) or serotonin, either by inhibiting the uptake of such neurotransmitters by inhibiting their metabolism, or by causing increased release. Thus tricyclic antidepressants, like imipramine (IMI) and amitriptyline (AMI) and their metabolites inhibit amine uptake. Monoamine oxidase inhibitors (MAOI), like phenelzine (PHZ) and parnate (PAR), inhibit amine metabolism, and treatment with electroconvulsive therapy (ECT) causes increased release of such amines. The antidepressant drugs thus increase the postsynaptic concentrations of amines and potentiate transmitter function. This presumed mode of action of antidepressant drugs does not explain, however, the delayed onset of clinical effects after the initiation of antidepressant therapy and the antidepressant properties of such drugs as iprindole and Wellbatrin (WB) which do not alter amine uptake or metabolism.

The effect of treatment with antidepressant drugs on beta adrenergic receptor sensitivity has been widely studied, and it has been reported that most antidepressant drugs cause down regulation of the NE-coupled adenylate cyclase system (Vetulani et al. 1976) and beta adrenergic receptor sensitivity (Frazer et al. 1974) after chronic treatment. These effects have been related to the antidepressant properties of these drugs.

In order to further examine the role of beta adrenergic receptors in the mode of action of antidepressant drugs, the authors have studied the effect of treatment with some antidepressant drugs and neuroleptics on ^{3}H-dihydroalprenolol (^{3}H-DHA) binding in rat brain. Since it has been reported that certain antidepressant drugs block histamine receptors, the authors have also studied the effect of antidepressant treatment on histamine receptor mediated cyclic AMP accumulation in guinea pig cortex.

Antidepressant Treatment and Beta Adrenergic Receptors

It was first reported by Banerjee et al. (1977) that treatment with antidepressants caused a decrease in beta adrenergic receptor binding sites in rat brain as determined by ^{3}H-DHA binding. The authors in the current investigation examined the effect of chronic treatment with several other antidepressants on beta adrenergic receptor sensitivity in rat cortex by studying the binding of ligand ^{3}H-DHA. The experimental conditions and the results are listed in the Table. It was observed that treatment with desipramine (DMI) caused a significant reduction of the maximum number of ^{3}H-DHA binding sites (receptor density). These results are similar to those reported by Banerjee et al. (1977). Chronic treatment with ECT also caused a significant reduction in the maximum number of ^{3}H-DHA binding sites as previously reported by the authors (Pandey et al. 1979).

The authors examined the specificity of the effects of various antidepressant drugs on ^{3}H-DHA binding to the rat brain by studying the effect of some other classes of antidepressants such as IMI, the MAO inhibitor PHZ, the antidepressant WB, lithium (Li^+), and the neuroleptics, chlorpromazine (CPZ) and haloperidol (HP) (Pandey & Davis 1981). The antidepressant drugs IMI, PHZ, and WB, but not Li^+, caused a significant reduction in the maximum number of ^{3}H-DHA binding sites. Treatment with Li^+ produced a small reduction (14%) in ^{3}H-DHA binding, but this was not significantly different from the binding in control rats ($p < 0.07$, *t*-test, two-tailed just below level of significance).

To examine whether this reduction in receptor density caused by antidepressant treatment is related to a change in the affinity of ^{3}H-DHA binding, the authors calculated the apparent dissociation constant (K_d) of ^{3}H-DHA binding, as summarized in the Table. There was no significant change in the K_d of ^{3}H-DHA binding in

Table

Effect of Chronic Treatment with Antidepressants on Receptor Density (Maximum ^{3}H-DHA Bound) and Apparent Dissociation (^{3}H-DHA Binding) in Rat Brain

Treatment	Receptor Density ^{3}H-DHA Bound, (fmole mg Protein^{-1})	Percent of Control	*p* Values as Compared With Control	Dissociation Constant (nM)
Control (1)	119 ± 8.8	100		1.06
Desipramine	84 ± 3.5	71	<0.001	1.19
Imipramine	66 ± 9.0	56	<0.001	0.90
ECT	87 ± 3.5	73	<0.001	1.14
Phenelzine	87 ± 4.6	73	<0.001	1.19
Control (2)	—	100	—	0.90
Lithium	—	86	<0.07	0.97
Wellbatrin	—	74	<0.05	1.06
Cocaine	—	97	NS	
Haloperidol	—	97	NS	
Chlorpromazine	—	88	NS	

Groups of male Sprague-Dawley rats (100-150 g) were given one of the following treatments for 12-14 days: Desipramine (10 mg/kg), imipramine (20 mg/kg), phenelzine (10 mg/kg), WB (60 mg/kg), cocaine (10 mg/kg), haloperidol (5 mg/kg), or chlorpromazine (10 mg/kg) were administered once daily b.i.p. injection and lithium chloride (4 m Eq/kg) twice daily. Control rats received normal saline ECT (75 MA for 1 sec) was administered through transcorneal electrodes once daily for 12 days and controls were treated similarly but did not receive the shock. The rats were killed 1 hr after the last treatment, and the cortices were removed, homogenized in 50 volumes (w/v) of Tris buffer (0.05 M, pH 7.4), and spun at 49,000 g for 10 min. This process was repeated, and the pellet was finally suspended in Tris buffer. Binding of ^{3}H-DHA was carried out in triplicate by incubation of an aliquot of the suspension (0.3-0.5 mg protein) with ^{3}H-DHA at three concentrations (between 0.4 and 4 nM) in Tris buffer in a final volume of 1 ml, with or without 1 μM (−) propranolol, at 23 °C for 15 min. ^{3}H-DHA bound to the memurane was separated by filtration through a Whatman (GF/F) filter and washed three times with 4 ml buffer. The filter was placed in a BBS cocktail and counted in a Nuclear Chicago scintillation spectrometer. Specific binding is defined as the difference between total binding and the binding observed in the presence of 1 μM (−) propranolol. Receptor density and K_d values were calculated by Scatchard analysis: *p* values were obtained by paired *t*-test (two-tail). Each group of treatment consisted of 6-8 rats.

animals streated with antidepressants as compared to the control group, indicating that a reduction in the maximum number of ^{3}H-DHA binding sites is not attributable to a change in the affinity of these binding sites.

In order to examine if a decrease in ^{3}H-DHA binding is specific to treatment with antidepressant drugs, the authors examined the effect of treatment with neuroleptic drugs HP and CPZ and the psychomotor stimulant cocaine which, like tricyclic antidepressant drugs, is a potent inhibitor of amine uptake. Neither treatment with HP and CPZ nor with cocaine caused any significant changes in ^{3}H-DHA binding as shown in the Table. These results thus indicated that antidepressant drugs may share a common property of reducing beta adrenergic receptor sensitivity after chronic treatment.

Antidepressant Treatment and Histamine Receptors

Treatment with antidepressant drugs causes alterations in several of the monoamine receptors. It was reported by Green and Mayaani (1977) and Kanof and Greengard (1978) that antidepressant drugs are potent blockers of histamine receptors in the brain under *in vitro* conditions. In order to examine if treatment with antidepressant drugs causes changes in histamine receptor sensitivity, the authors studied the effects of treatment with antidepressant drugs on histamine receptor mediated cyclic AMP accumulation in guinea pig cortex.

Groups of male guinea pigs were injected intraperitoneally (i.p.) with the drugs as indicated (Figure 1) or with normal saline either once daily for 15 days for chronic studies or once for acute studies. The animals were then sacrificed either 1 hour or 24 hours after the last treatment. Histamine-stimulated accumulation of ^{3}H-cyclic AMP in slices of guinea pig cortex that had been prelabelled with ^{3}H-adenine was used as an index of adenylate cyclase-coupled histamine receptor sensitivity by the procedure described by Pandey et al. (1982).

The effects of chronic treatment (15 days) with antidepressant drugs on histamine-stimulated accumulation of ^{3}H-cyclic AMP in the guinea pig cortex obtained when the animals were killed 1 hour after the last injection are shown in Figure 1. For the purpose of graphical display, histamine stimulated ^{3}H-cyclic AMP accumulation in treated animals has been expressed as percent of ^{3}H-cyclic AMP accumulation of control animals. The differences between control and treated animals were not significant in the basal accumulation of ^{3}H-cyclic AMP (without histamine), although it tended to be lower in treated animals. Histamine (10^{-5}M, 10^{-4})-stimulated accumulation of ^{3}H-cyclic AMP in the cortical slices obtained from guinea pigs that were chronically treated with AMI, DMI, or PHZ was significantly lower than that in the control animals. However, histamine-stimulated accumulation of ^{3}H-cyclic AMP in the slices obtained from guinea pigs treated with CPZ, which has been shown to be a potent blocker of histamine H_2 receptors *in vitro* (Kanof & Greengard 1978), was not significantly different from that in the control animals. Similar results

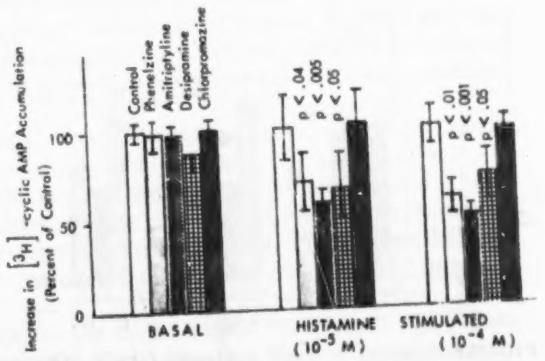

FIGURE 1. Effect of chronic treatment with antidepressants on ^{3}H-cyclic AMP accumulation in cortical slices obtained from guinea pigs sacrificed 1 hour after last injection. Groups of guinea pigs ($N = 7$ in each group) were injected i.p. with amitriptyline (8 mg/kg), phenelzine (15 mg/kg), desipramine (10 mg/kg), chlorpromazine (10 mg/kg), or normal saline (equal volume once daily for 15 days). One hour after the last treatment the animals were killed, and the cerebral cortex was immediately removed from the brain. Accumulation of ^{3}H-cyclic AMP in the absence (basal) or presence of histamine was then determined for each animal. In each set of experiments, treated guinea pigs were paired with control giunea pigs. Since the experiments were conducted in different sets, the results for treated animals have been expressed as percent of ^{3}H-cyclic AMP accumulation relative to controls. The data were analyzed by a *t*-test for two independent groups; *p* values (two-tailed) expressed above are those compared to control animals.

were obtained when animals treated for 15 days were sacrificed 24 hours after the last treatment, thus indicating that the effects persist at least up to 24 hours after the termination of the treatment as reported earlier (Pandey et al. 1982).

For acute studies, animals were given single administration of the drugs as indicated and were sacrificed 1 hour after treatment for cyclic AMP accumulation studies. The basal accumulation of ^{3}H-cyclic AMP in the slices obtained from guinea pigs treated acutely with antidepressants was similar to that in control animals, as shown in Figure 2. The accumulation of ^{3}H-cyclic AMP in the presence of histamine (10^{-5}M, 10^{-4}M) was significantly lower in the slices obtained from the animals acutely treated with AMI and DMI, but not in animals treated with PHZ, indicating that the effect of acute treatment with PHZ differs form its effect under chronic conditions.

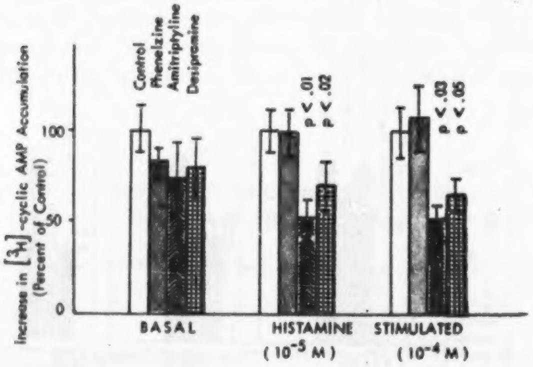

FIGURE 2. Effect of acute treatment (single injection) with antidepressants on ^{3}H-cyclic AMP accumulation in guinea pig cortical slices.

These studies thus indicate that treatment with antidepressant drugs causes a decrease in histamine receptor response in guinea pig cortex. The decrease observed after acute treatment with tricyclic antidepressants may be related to the histamine receptor-blocking properties of these drugs. The effects observed after chronic treatment appears to be related to adaptive changes in the histamine receptor-adenylate cyclase system because PHZ, which is a weak inhibitor of histamine receptors *in vitro*, produces a decrease in histamine-stimulated ^{3}H-cyclic AMP accumulation after chronic but not acute treatment. It therefore appears that at least two different mechanisms may be associated in decreasing histamine sensitive accumulation of ^{3}H-cyclic AMP accumulation in guinea pig cortex.

In summary, the results reported in this paper indicate that chronic treatment with antidepressant drugs causes a decrease in beta adrenergic receptor sensitivity in rat brain and histamine receptor mediated cyclic AMP accumulation in guinea pig cortex. Whereas the role of the histamine receptor in the mode of action of antidepressant drugs remains unclear, the results reported by the authors and other groups of investigators indicate a close relationship between changes in central beta adrenergic receptor sensitivity and antidepressant effects of these drugs. Further work is obviously needed for a better understanding of the molecular mechanisms associated with the mode of action of antidepressant drugs.

Assessment of Adrenergic and Serotonergic Receptor Function: Implications for the Etiology and Treatment of Depression[1]

Dennis S. Charney, M.D.,[2] and George R. Heninger, M.D.[2]

Recent studies conducted in laboratory animals have provided the basis for several hypotheses relating alterations in adrenergic and serotonergic receptor function to the etiology and treatment of affective illness. Long-term antidepressant (AD) treatment has been shown to decrease the functional sensitivity of alpha-2 and beta adrenergic receptors and to increase the functional sensitivity of alpha-1 adrenergic receptors and serotonergic (5-HT) receptors. (For review, *see* Charney et al. 1981b).

Although it is not possible in human studies to utilize the invasive electrophysiologic and pharmacologic strategies used in animals to develop such hypotheses, several useful methods to assess the clinical relevance of serotonin and noradrenergic receptor function have recently been developed. One method is to design and determine the efficacy of treatment approaches which, based on preclinical investigations, have specific effects on adrenergic and serotonergic receptor function. Another is to use "receptor challenge" paradigms to assess the physiological, biochemical, and behavioral effects of centrally active neurotransmitter receptor agonists and antagonists in healthy controls and depressed patients before and during long-term AD treatment. Recent data obtained from a series of investigations indicate that use of these strategies allows testing of specific receptor hypotheses developed from laboratory animal studies and facilitates the development of improved treatments for patients refractory to standard treatments.

Receptor Challenge Paradigms

Presynaptic Alpha-2 Adrenergic Receptors

This receptor is located both presynaptically and postsynaptically. There is considerable evidence that the presynaptic alpha-2 adrenergic receptor plays a major role in the modulation of central noradrenergic activity by regulating the release of norepinephrine (NE) through a negative feedback mechanism (Cedarbaum & Aghaajanian 1977; Langer et al. 1980; Nyback et al. 1975). Activation of this receptor by alpha-2 adrenergic receptor agonists, such as clonidine, decreases NE impulse flow and turnover (Anden et al. 1976; Cedarbaum & Aghajanian 1977; Svensson & Usdin 1978). Conversely, the alpha-2 adrenergic antagonists, yohimbine and piperoxane, increase NE impulse flow and turnover (Cedarbaum & Aghajanian 1976; Scatton et al. 1980). Consequently, measurement of the effect of alpha-2 adrenergic receptor agonists and antagonists on NE turnover may provide an index of presynaptic alpha-2 adrenergic receptor sensitivity.

The effects of clonidine on behavior, blood pressure, and plasma free 3-methoxy-4-hydroxyphenylethylene glycol (MHPG) in healthy subjects have recently been determined in two separate investigations. Plasma-free MHPG was used as an index of central NE turnover because it has been shown to reflect brain MHPG, the major metabolite of brain NE (Maas et al. 1979; Elsworth et al. 1982). In the first study of 11 male subjects (mean age 28 yrs., range 21-34), oral clonidine (5 μg/kg) produced a 22 percent decrease in plasma-free MHPG 3½, 4, and 5 hours after the dose in comparison to placebo ($p < .01$) (Leckman et al. 1980, unpublished data). In a second sample of 6 male and 6 female subjects (mean age 40 yrs., range 27-57), clonidine (5 μg/kg) produced a 19 percent decrease in mean plasma-free MHPG 3-½, 4, and 5 hours following the dose in comparison to placebo ($p < .05$) (Charney et al. 1982b). In both studies, clonidine also significantly decreased blood pressure and produced behavioral sedation. Thus, the results of the second healthy subject investigation replicated the findings of the original study and supported the reliability of this test as a possible measure of the presynaptic alpha-2

adrenergic receptor system.

A study assessing the effects of oral yohimbine on plasma-free MHPG, cardiovascular function, and behavior in eight healthy subjects has recently been completed. Administration of three doses of oral yohimbine (10, 15, and 20 mg) produced significant increases in mean plasma-free MHPG levels of 33, 33, and 66 percent, respectively, 3 and 4 hours after the dose compared to placebo (Charney et al. 1982a). The 15 and 20 mg yohimbine doses induced significant but clinically safe increases in systolic blood pressure and autonomic symptoms such as piloerection and rhinorrhea. The 20 mg yohimbine dose produced a modest but significant increase in self-rated anxiety. Taken together, the results of these studies indicated that determination of the effects of clonidine and yohimbine on plasma-free MHPG may be a useful method to examine the functional sensitivity of presynaptic alpha-2 adrenergic receptors in depressed patients.

The ability of antidepressant drugs, such as desipramine (DMI), to induce a subsensitivity of the alpha-2 adrenergic receptor may have important implications regarding the mechanism of action of antidepressant drugs and the catecholamine hypothesis of depression (Charney et al. 1981b). To determine whether desipramine induces a subsensitivity in alpha-2 adrenergic receptor sensitivity in depressed patients, the effect of clonidine and clonidine placebo on plasma MHPG in 10 depressed patients was evaluated before and during long-term DMI treatment (Charney et al. 1981a). Long-term DMI treatment significantly attenuated the effects of clonidine on plasma-free MHPG. Prior to DMI treatment, clonidine decreased plasma-free MHPG by 25 percent compared to placebo ($p < .05$). During desipramine treatment, the clonidine-induced decrease in MHPG was only 11 percent and was significantly less than the comparable decrease in MHPG levels observed prior to treatment ($p < .05$). DMI treatment also produced a 36 percent decrease in baseline plasma-free MHPG compared to pretreatment levels ($p < .01$). In the 10 patients studied, there was no association among therapeutic response, pretreatment MHPG level, and clonidine effects on MHPG and blood pressure either prior to or during DMI treatment.

The findings of the study are consistent with the results of previous animal studies that central alpha-2 receptor subsensitivity develops with long-term DMI treatment. However, what is left unanswered and requires further investigation is whether DMI's ability to reduce alpha-2 adrenergic receptor sensitivity is a necessary condition for antidepressant efficacy. The decreased plasma MHPG level during DMI treatment suggests that the reduced NE turnover in the depressed patients studied may reflect the relative balance between the inhibition of NE neuronal firing rate and enhancement of NE released per impulse induced by long-term desipramine treatment. The development of the alpha-2 adrenergic receptor subsensitivity and consequent increased NE release per impulse may be insufficient to overcome the persistently decreased impulse flow.

It has been suggested that a subgroup of depressed patients may have hypersensitive presynaptic alpha-2 adrenergic receptors resulting in decreased synaptic NE and neuronal transmission (Leckman et al. 1980; Charney et al. 1981a). To evaluate this hypothesis, the effects of clonidine on plasma-free MHPG and blood pressure were evaluated in 15 depressed patients and 12 healthy subjects of similar age and sex (Charney et al. 1982b). Following placebo clonidine, the increase in plasma-free MHPG in the controls was significantly greater than the small decrease in the patients (+0.7 vs. −0.1 ng/ml, $p < .05$). In addition, the decrease in plasma-free MHPG in the patients following active clonidine was significantly greater than the response to active clonidine in the controls (−0.9 vs. +0.1 ng/ml, $p < .01$). However, of central importance is the finding that there was no significant difference between the patients and the controls in the overall "net" effect of clonidine on plasma-free MHPG (i.e., when the effect of placebo clonidine is subtracted from the active clonidine effect the controls had a "net" clonidine induced decrease of 0.6 ng/ml while in the patients there was a "net" decrease of 0.8 ng/ml, a nonsignificant difference). The decreases in blood pressure induced by clonidine were not different between the healthy subjects and the depressed patients.

The findings of this study did not provide support for the hypothesis that depressed patients have hypersensitive presynaptic alpha-2 adrenergic receptors. The ability of clonidine to decrease NE turnover was not different in depressed patients and healthy controls similar in age and sex.

In addition, clonidine induced similar decreases in blood pressure in both groups. This study did reveal several potentially important differences in NE function between the depressed patients and the healthy controls. When considered separately, the plasma-free MHPG response to placebo clonidine and active clonidine were significantly different between the two groups. One explanation for the different MHPG responses of depressed patients and healthy subjects to placebo and clonidine are that the two groups differ in the circadian secretion of MHPG. Wehr et al. (1980) reported that depressed patients were phase advanced in their urinary MHPG circadian rhythm compared to normal subjects. Therefore, in the present investigation, while the plasma MHPG levels of the healthy subjects are rising during the time period of the test day (8 a.m. to 3 p.m.), the MHPG levels of the patients may have peaked earlier and then remained stable. Clonidine simply lowered plasma MHPG an equal amount in both groups. The differences in diurnal MHPG secretion may reflect abnormalities in NE synthesis or metabolism or in the sensitivity of other receptors aside from the presynaptic alpha-2 adrenergic receptor.

Studies are now in progress in healthy subjects and depressed patients before and during AD treatment to determine whether the same assessment of alpha-2 adrenergic receptor sensitivity obtained with clonidine is also observed with yohimbine.

Postsynaptic Alpha-2 Adrenergic Receptors

The ability of clonidine to increase growth hormone secretion appears to be due to stimulation of postsynaptic alpha-2 adrenergic receptors in the hypothalamus (Terry & Martin 1981). Several groups of investigators (Charney et al. 1982b; Checkley et al. 1981; Mattusek et al. 1980) have demonstrated that oral and intravenous clonidine results in significant increases in growth hormone secretion in healthy subjects. These findings indicate that this effect of clonidine may be used as an index of postsynaptic alpha-2 adrenergic receptor function. The growth hormone response to clonidine has been shown to be blunted in drug-free depressed patients compared to healthy subjects, suggesting that the sensitivity of postsynaptic alpha-2 adrenergic receptors may be decreased (Charney et al. 1982b; Checkley et al. 1981; Mattusek et al. 1980). The effect of DMI and amitriptyline on the growth hormone response to clonidine was studied in 12 depressed patients to determine whether the blunted pretreatment response normalized following long-term treatment (Charney, et al., in press-b). The AD treatments did not alter the growth hormone response to clonidine in either treatment responders or nonresponders. Thus, while the etiologic significance of the blunted pretreatment growth hormone response remains to be determined, it does not appear that the efficacy of AD agents is dependent upon increasing the sensitivity of the postsynaptic alpha-2 adrenergic receptors.

Postsynaptic Serotonin Receptors

Despite the evidence that serotonin (5-HT) containing neurons in the central nervous system are involved in the regulation of a variety of brain functions, few paradigms have been developed that are capable of assessing brain 5-HT function in human subjects. In order to develop a method capable of evaluating central 5-HT function, the effects of intravenous tryptophan (6-7 grams) administered over 20 minutes on the secretion of prolactin, growth hormone, and mood state were studied in 10 healthy subjects (Charney et al. in press-a). The tryptophan infusion induced robust increase in prolactin in all 10 subjects with a peak occurring 60 minutes after the start of the infusion. Prolactin levels increased from a baseline of 9.6 +/− 1.4 ng/ml to a peak of 32.6 +/− 6.3 ng/ml ($p < .01$). A significant but variable increase in growth hormone concentration was observed, with the peak increase also occurring 60 minutes following the infusion (1.0 +/− .3 to 12.1 +/− 6.0 ng/ml, $p < .01$). The subjects reported feeling significantly more 'high,' 'mellow,' and 'drowsy' following the infusion in comparison to placebo ($p < .01$). These results, considered in conjunction with animal studies demonstrating that the ability of 5-HT to increase prolactin is potentiated by treatments which increase postsynaptic 5-HT sensitivity (Kuhn et al. 1981), suggest that study of the effects of intravenous tryptophan may be a means of assessing central postsynaptic 5-HT receptor function in depressed humans. Studies are now in progress in patients to determine the effects of a variety of AD treatments on the actions of intravenous tryptophan.

Treatment Approaches Based Upon the Receptor Sensitivity Model of Antidepressant Action

The identification of changes in postsynaptic beta, alpha-1, and 5-HT receptor function has proven useful in the development of new treatment strategies (Table). It has been suggested that the decrease in beta adrenergic receptor density induced by long-term AD administration may be a good screening test for AD activity. Two recent reports indicate an accelerated development of beta adrenergic receptor subsensitivity when desipramine is combined with the alpha adrenergic antagonists phenoxybenzamine and yohimbine (Paul & Crews 1980; Ursillo et al. 1980). If beta receptor binding alterations are related to AD efficacy, one might expect the clinical response to such a combination to be accelerated. To test this hypothesis, an ongoing investigation is evaluating the therapeutic effects of a yohimbine-desipramine and a yohimbine-amitriptyline combination in depressed patients. The preliminary findings of this study indicate that these combinations can be given safely to human subjects and should provide a valid assessment of the role of beta adrenergic receptor changes in the therapeutic actions of AD agents.

Table

Therapeutic Implications of Receptor Sensitivity Model

Antidepressant-induced Receptor Alteration	Treatment Strategy*
Decreased beta adrenergic receptor sensitivity	Yohimbine-antidepressant combination
Increased alpha-1 adrenergic receptor sensitivity	Thyroid hormone-antidepressant combination
Increased 5-HT receptor sensitivity	Lithium-antidepressant combination

*See text for details.

A similar approach of attempting to enhance the AD-induced receptor changes has recently been exploited. In a recent report, deMontigny et al. (1981) described eight patients with major unipolar depressions who failed to respond to AD treatment. All eight patients had a marked reduction in symptoms within 48 hours after lithium carbonate was added to their AD regimen. The remarkable improvement in the eight patients was attributed to an enhancement by lithium of central 5-HT systems that acted synergistically with the AD-induced sensitization of 5-HT postsynaptic receptors. To replicate and extend these findings, a placebo-controlled, double-blind investigation of the ability of lithium to potentiate the effects of a variety of AD drugs in treatment refractory patients has recently been conducted (Heninger & Charney, submitted for publication). The results of this study, while strongly supporting the original findings of deMontigny et al. (1981), indicate the therapeutic activity of lithium is not universal, and in some patients this effect may begin to appear only after a minimum of 4 to 7 days of lithium treatment. Clearly, more studies are needed to answer the questions: What type of patients respond most favorably to lithium potentiation? When is the best time to add lithium to an ongoing AD regimen? How long must lithium be continued to maintain a therapeutic response?

The ability of thyroid hormone to accelerate and potentiate the effects of a variety of tricyclic antidepressants has recently received renewed attention (Goodwin et al. 1982). This effect of thyroid hormone may be due to increased sensitivity of alpha-1 adrenergic receptors. Recent animal investigations indicate that thyroid hormone increases the number of alpha-1 adrenergic receptor binding sites in the cerebral cortex (Grob et al. 1981) and the behavioral responses to central postsynaptic alpha adrenergic receptor stimulation (Strombom et al. 1977).

The monoamine receptor sensitivity hypothesis provides a heuristic framework from which to develop clinical research strategies in depressed patients that may generate new insights into the pathophysiologic processes of depressive illness and to the development of improved therapeutic agents. The results decribed above are evidence of this and illustrate the benefits that occur when findings from basic neuroscience are applied to clinical treatment.

Protein Phosphorylation and Synaptic Mechanisms

Chair: Walter M. Lovenberg, Ph.D.
Hypertension Endocrine Branch
National Heart and Lung Institute
Bethesda, Maryland

Introductory Comments

Walter Lovenberg, Ph.D.[1]

Protein phosphorylations appear to play key roles in neurotransmission and the response of cells to neurotransmitters. A number of protein kinases have been identified in brain and these are known to phosphorylate proteins in several subcellular elements. There appear to be three basic types of protein kinases (cyclic nucleotide dependent, Ca^{+2}-calmodulin· dependent, and Ca^{++}-cyclic nucleotide independent) although each of these may exist in various molecular forms. The fact that at least some of the kinases appear to be activated by limited proteolysis tends to make exact characterization of these enzymes difficult. The second messengers cAMP and Ca^{++} are ideally suited for interneuronal communication, since Ca^{++} fluxes are an integral part of neuronal transmission and neuronal membranes are rich in adenylate cyclase. It would appear that at least in certain instances these adenylate cyclases are coupled to neurotransmitter receptors.

Phosphorylation of Cell Membranes. If one incubates synaptic plasma membranes purified from rat brain with Mg^{++} and adenosine triphosphate (ATP) labeled with ^{32}P, a number of protein bands resolved on slab gel electrophoresis are labeled. Autoradiographs of the proteins solubilized from such an incubation indicate that these proteins range in molecular weight from 40K to over 100K. Addition of cAMP to the phosphorylation reaction results in an increase in incorporation of PO_4 into selective bands. Particularly prominent are two bands with molecular weights in the range of about 80,000. These protein stubstrates have been extensively characterized be Greengard and his colleagues (Ueda & Greengard 1977) and were originally termed protein Ia and Ib. More recently they have been localized primarily to synaptic vesicles, and it has been suggested that they be called synapsin. Calcium also stimulates the incorporation of ^{32}P into a number of specific proteins in the presence of calmodulin. Protein I is also a substrate for the Ca^{++}-calmodulin dependent protein kinase. It would appear that each of the kinases act at specific sites (Huttner & Greengard 1979).

The physiologic role for phosphorylation of neuronal specific membrane proteins remains to be defined, although changes in ion permeability, receptor function, and neurotransmitter release are likely candidates.

Cytosolic Phosphorylation. Some of the functions of cytosolic protein kinases have been well defined. In many instances these kinases are involved in regulating the activity of cytosolic enzymes. The regulation of phosphorylase by protein kinase has been well studied. Studies in our laboratory and others indicate that the synthesis of the catecholamines and serotonin may be regulated by phosphorylation of their biosynthetic enzymes. Both Ca^{++} and cAMP-dependent kinases play important roles in these systems.

[1] Section on Biochemical Pharmacology, Hypertension-Endocrine Branch, National Heart, Lung, and Blood Institute, Bethesda, MD 20205.

With regard to tyrosine hydroxylase, we initially showed that the enzyme could be activated in the presence of a cAMP-dependent protein kinase and protein phosphorylating conditions. This activation at pH 6.0, the pH optimum of the enzymic reaction, appeared to be due to an increased affinity for the cosubstrate, tetrahydrobiopterin, and a decreased affinity for the end-product (dopamine). To understand whether protein phosphorylation represented a significant physiologic control mechanism, it seems important to know the relative concentration of tyrosine hydroxylase and its cosubstrates within the neuron. Also, knowledge of the kinetic properties of the enzyme at a physiological pH was necessary. By a variety of techniques with specific brain lesioning and enzyme kinetics we have been able to suggest a model for the regulation of dopamine synthesis in a dopamine neuron (Levine et al. 1981). By estimating the concentration of enzyme subunits and hydroxylase cofactor concentration in the terminal to be about 100 μM each, and by understanding the kinetics of the phosphorylated and non-phosphorylated enzyme at physiologic pH, we can conclude that a cyclic AMP-dependent phosphorylation of tyrosine hydroxylase converts an essentially inactive enzyme to a fully active form.

Protein phosphorylation may also play an important role in the regulation of tryptophan hydroxylase. We know far less about this system which is specifically present in serotonergic neurons. In contrast to tyrosine hydroxylase this enzyme can only be activated by Ca^{++} calmodulin-dependent protein kinase (Kuhn et al. 1980). At this stage little is known about the regulation of tryptophan hydroxylase *in vivo*, altough protein phosphorylation is likely involved.

The Possible Role of Phosphorylation of Tyrosine Hydroxylase in Catecholaminergic Neurons[1]

Mitchell A. Lazar, Ph.D., M.D.,[2] and
Jack D. Barchas, M.D.[2]

Tyrosine hydroxylase (TH) catalyzes the rate-determining step in the biosynthesis of catecholamines (Levitt et al. 1965). The regulation of TH activity is therefore a major determinant of the quantitative aspects of catecholaminergic neurotransmission. TH can be phosphorylated by cAMP-dependent (Edelman et al. 1981; Joh et al. 1978; Markey et al. 1980; Vulliet et al. 1980), and independent (Raese et al. 1979; Yamauchi & Fujisawa 1981), protein kinases, resulting in kinetic activation of the enzyme. It has been proposed that *in vivo* activation of TH during conditions of increased neuronal firing rate may be mediated by phosphorylation of the enzyme (Weiner et al. 1978; Lazar et al. 1981a). The adequacy of phosphorylation of TH for the short-term control of catecholamine synthesis is the subject of the present paper. A hypothesis concerning the role of TH phosphorylation in neuronal homeostasis is also presented.

Studies of purified bovine striatal TH have elucidated the kinetic properties of the non-phosphorylated and phosphorylated forms of the enzyme (Lazar et al. in press). At representative concentrations of dopamine and BH$_4$, K$_m$, K$_i$, and V$_{max}$ values of TH at pH 7.0 can be used to theoretically calculate the relative activities of nonphosphorylated and phosphorylated TH in a dopaminergic neuron (Lazar 1980). Such calculations are tabulated in the Table.

100	40	0.24	5.45	22.7

(BH$_4$) and (Dopamine) are in μM. V(Velocity) is in nmoles DOPA formed per minute per milligram TH. V(Non-P) and V(Phos) refer to calculated rates of reactions catalyzed by nonphosphorylated and phosphorylated TH, respectively. Estimates of BH$_4$ concentration are from Lloyd and Weiner (1970) and Levine, Kuhn, and Lovenberg (1979). Estimates of dopamine concentration are from Mefford, Gilber, and Barchas (1980), and the range shown takes into account the fact that only about 40% of neuronal dopamine is bound to sedimentable material (Whittaker 1966). Intraneuronal pH has been estimated to be approximately 7.1 by Vigny, Hultorel, Henry, and Pantaloni (1980).

It can be seen that in the range of likely intracellular concentrations of dopamine and BH$_4$, activation of TH by phosphorylation would be on the order of 8-33 fold, if all TH molecules were phosphorylated. This would be expected to cause a major increase in the rate of catecholamine synthesis, but nevertheless some time would be necessary before the increase in catecholamine synthesis had an effect on the absolute concentration of dopamine concentration within the nerve ending. Thus it is doubtful that the function of increased dopamine synthesis is to replenish the cell with the amount of catecholamine lost during neurotransmission. Yet, it appears that short-term activation of TH occurs during periods of nerve firing, and that this activation is quantitatively similar to the activation induced by phosphorylation of the TH molecule (Masserano & Weiner 1979). The physiological relevance of TH phosphorylation may relate to the observations that newly synthesized catecholamines, including norepinephrine (Kopin et al. 1968) and dopamine (Glowinski 1970), are preferentially released during nerve stimulation.

A dopaminergic nerve terminal is schematically represented in the Figure. Numbers in parenthesis in the text refer to the correspondingly numbered steps in the Figure. Kinetic properties of purified bovine striatal TH, which were used to generate the calculation in the Table, are shown in the Figure (Lazar et al. 1982). It is proposed that phosphorylation would increase the rate of DOPA formation as discussed above (1). As TH is the rate-limiting step in catecholamine synthesis, immediate decarboxylation of DOPA (2) would result in an increased rate of dopamine synthesis. Dopamine exists in three intracellular forms, which may or may not be experimentally indistinguishable: a) cytoplasmic, which serves to inhibit TH, b) stored, not for immediate release (3), and c) available for release (4). Presumable in times of active nerve firing more newly synthesized dopamine is channeled to the releasable pool than in times of relative inactivity.

Intracellular calcium increases as a result of nerve stimulation (5). Calcium (6) is absolutely required for release of transmitter (7). In addition, calcium influx has also been shown to result in activation of a Ca^{+2}-dependent protein kinase (8), possibly via calmodulin (Schulman & Greengard 1978). Calcium-dependent protein phosphorylation has been speculated to play a role in transmitter release (DeLorenzo et al. 1979). It is hypothesized here that calcium-dependent phosphorylation may be involved in TH activation *in vivo* (9). Raese et al. (1979) have shown that cyclic AMP-independent protein kinase may also activate TH, and it has been recently suggested that calcium-dependent phosphorylation may also activate the enzyme (Yamauchi & Fujisawa 1980). If this were the case in vivo, calcium-dependent phosphorylation would promote both the increased release of neurotransmitter and the increased synthesis of transmitter available for release. Thus one intracellular event, the increase in calcium concentration, may rapidly result in neurotransmitter synthesis and neurotransmission, with little compromise of the cell's ability to respond to further stimuli. Phosphorylation of TH by cAMP-dependent protein kinase (10) may also serve a physiological role as a parallel method of increasing catecholamine synthesis.

HYPOTHESIZED ROLE OF PHOSPHORYLATION IN THE REGULATION OF TYROSINE HYDROXYLASE ACTIVITY DURING STIMULI RESULTING IN INCREASED NEURONAL FIRING RATE

FIGURE. Schematic dopaminergic neuron. Numbered steps are referred to in text. Pluses and minuses refer to activating and inhibiting steps, respectively. The activities shown for phosphorylated (TH-PO$_4$) and non-phosphorylated TH refer to the ratio of TH activity at pH 7to that at pH 6.0, the *in vitro* pH optimum of non-phosphorylated TH. Estimates of dopamine, BH$_4$, and hydrogen ion concentrations are derived from the references to the Table.

Once TH is activated there are two hypothesized mechanism of inactivation of the enzyme. Thermal stability of the phosphorylated form of the enzyme is significantly less than that of the nonphosphorylated form of TH (Lazar et al. 1981b). If this correlates with *in vivo* turnover rate (Bond 1975), phosphorylated TH may be degraded faster than nonphosphorylated TH (11, Kd_2 greater than Kd_1). This could serve to time limit the activation process. In addition, phosphorylated TH may be susceptible to dephosphorylation (12), possibly by a phosphatase with some specificity for TH (Lazar et al. 1978).

If degradation of TH is involved in the regulation of levels of phosphorylated TH, then after a number of stimuli there might be depletion of TH molecules. However, there is ample evidence that long-term stimulation produces induction of TH synthesis in the cell body (13), possibly by transsynaptic induction (Thoenen 1975). Thus there exists a mechanism to increase the number of nonphosphorylated TH molecules after periods of sustained nerve stimulation.

In summary, phosphorylation produces a number of significant kinetic changes in TH. The phosphorylated form of the enzyme appears more suited to the intraneuronal milieu than is the nonphosphorylated form of TH. This magnifies the effect of phosphorylation of TH on *in vivo* catecholamine synthesis. The relative inhibition of nonphosphorylated TH under physiological constraints is what may enable the cell to regulate catecholamine synthesis quickly with relatively little overall change in the internal milieu. If, as suggested, calcium influx and calcium-dependent phosphorylation link nerve stimulation, transmitter release, and synthesis of transmitter for release, then the phosphorylation of tyrosine hydroxylase may play a crucial homeostatic role in the regulation of catecholaminergic neurons.

Calcium-Dependent Phosphorylation and the Regulation of Serotonin Synthesis

Donald M. Kuhn, Ph.D.[1]

Introduction

The brain is a major organ system which is comprised of over 10 billion heterogenous cells and driven by over 300 trillion connections and interconnections among these cells. Dysfunction of the brain presents a difficult problem in diagnosis and treatment. Not surprisingly, *brain* dysfunction manifests itself in many ways along a broad continuum of psychiatric disorders, most of which remain poorly understood. However, the results of a great deal of research are providing clues into the etiology of some psychiatric illnesses. A major focus for much research into psychiatric disorders centers on the chemistry of the neurotransmitter systems and one such neurotransmitter, serotonin (5-HT), is the subject of the present discussion. The reader only has to examine this volume to realize that 5-HT is still implicated in a variety of psychiatric disorders, not the least of which include depression and schizophrenia. This chapter will concentrate on the control of 5-HT synthesis and the role of phosphorylating mechanisms in this process.

The biosynthetic pathway for 5-HT begins with the conversion of the essential amino acid l-tryptophan (TRY) to 5-hydroxytryptophan (5-HTP) and is completed by the decarboxylation of 5-HTP (by l-aromatic amino acid decarboxylases) to 5-HT. The first step, TRY → 5-HTP, is catalyzed by tryptophan hydroxylase which is also the rate limiting step in 5-HT synthesis, and this reaction takes place exclusively in a very small proportion of cells in the brain. This is known as the 5-HT neuronal system. Since tryptophan hydroxylation is the initial and rate limiting step in 5-HT synthesis, the rate of this reaction can have a profound influence on the amount of 5-HT produced. Therefore, the present discussion will deal exclusively with the control of tryptophan hydroxylase activity. Furthermore, the role of phosphorylation in controlling 5-HT synthesis will focus, by necessity, on the rate-limiting hydroxylation step. These restrictions by no means lessen the importance of numerous other aspects of 5-HT synthesis and control (e.g., levels of substrates, release or uptake of 5-HT, 5-HT receptors) nor do they indicate that a phosphorylation reaction is the only means by which tryptophan hydroxylase is controlled.

Phosphorylation reactions are mediated by protein kinase enzymes which, in general, involve the transfer of the terminal phosphate from adenosine triphosphate (ATP) to some substrate (e.g., another enzyme or protein) via a covalent linkage. Perhaps the most extensively studied protein kinases are the ones which are dependent on cyclic nucleotides (cAMP or cGMP) for activity whereas, more recently, a number of protein kinases have been discovered to be dependent on calmodulin (CaM), the calcium-binding protein

---

(*see* Cheung 1980), for expression of catalytic activity. Furthermore, it appears that tryptophan hydroxylase is a substrate for Ca^{2+}-CaM dependent proteins kinase and that phosphorylating conditions activate tryptophan hydroxylase.

Method

Tryptophan hydroxylase was measured in extracts from rat mesencephalic tegmentum, since this brain section contains the majority of all cerebral 5-HT cell bodies and is rich in tryptophan hydroxylase activity. The enzyme was assayed by the fluorometric method described by Baumgarten et al. (1973) which involves the measurement of 5-HTP fluorescence after termination of the enzyme reaction. In order to study the effects of phosphorylation on tryptophan hydroxylase, ATP, Mg^{2+}, and calcium were added to the assay mixture. All reactions were carried out for 15 minutes at 37°C. Additional details on methodology are given in the following sections.

Results and Discussion

Effects of Phosphorylating Conditions on Tryptophan Hydroxylase Activity

Hamon et al. (1978) first observed that tryptophan hydroxylase could be activated by phosphorylating conditions and almost simultaneously Kuhn et al. (1978) reported similar observations. In these studies the addition of 0.5 mM ATP and 5.0 mM Mg^{2+} to the enzyme reaction mixture resulted in increased tryptophan hydroxylase activity when the assays were carried out with subsaturating concentrations of the substrate 2-amino-4-hydroxy-6-methyl-5,6,7,8 tetrahydrobiopterin (6-MPH_4). Lineweaver-Burk plots of kinetic data revealed that phosphorylating conditions decreased the apparent Km of tryptophan hydroxylase for the pteridine cofactor (6-MPH_4) without changing the Km for tryptophan. In fact, the Km for 6-MPH_4 was reduced from 210 to approximately 90 μM by phosphorylating conditions (Kuhn et al. 1978).

The requirements for activation of tryptophan hydroxylase appeared quite simple initially (Hamon et al. 1978; Kuhn et al. 1978). In addition to ATP and Mg^{2+}, only Ca^{2+} was necessary to allow complete activation. The Ca^{2+} requirement is demonstrated in Figure 1. This curve was generated by using a Ca^{2+}-EGTA buffer to control the levels of free Ca^{2+} (which can be calculated) and zero Ca^{2+} simply indicates the addition of excess EGTA without added Ca^{2+}. It can be seen that the reaction is sensitive to low concentrations of Ca^{2+} (10^{-7}–10^{-5} M Ca^{2+}) and the activation reaches half maximum at approximately 7.5×10^{-7} M Ca^{2+}. A number of cyclic nucleotides including CAMP and cGMP were tested and found to be inactive. Thus, the activation of tryptophan hydroxylase by phosphorylating conditions was apparently mediated by a cyclic nucleotide-independent but Ca^{2+}-dependent protein kinase. This total dependency on Ca^{2+} suggested that CaM might also be involved and the remaining discussion will concentrate on results with CaM and the phosphorylation induced activation of tryptophan hydroxylase. The interested reader is referred to previous, more detailed discussions on this subject (Kuhn et al. 1980).

The role of calmodulin in the activation of tryptophan hydroxylase by phosphorylating conditions. Cheung (1980) has identified several criteria which are

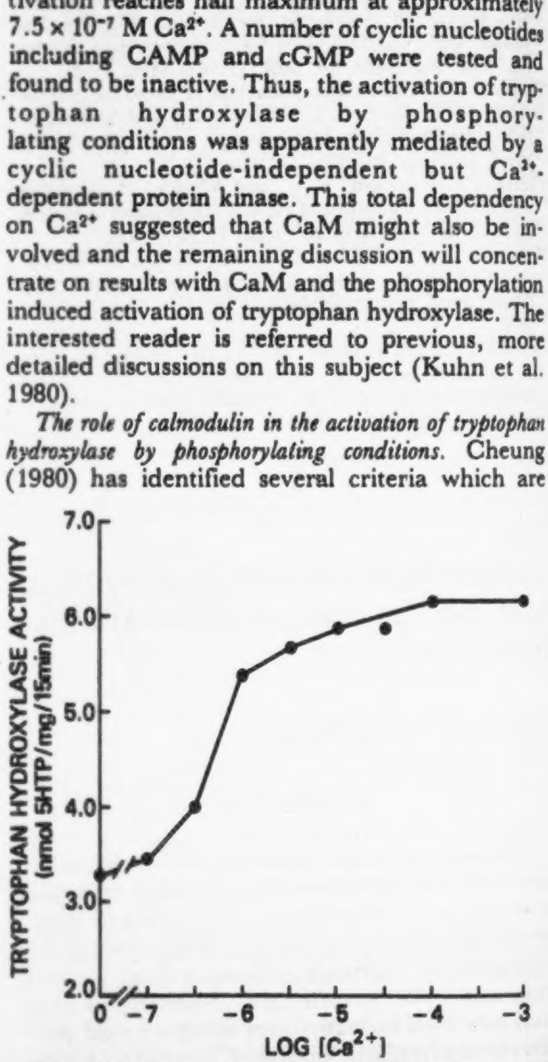

FIGURE 1. Calcium dependency of the activation of tryptophan hydroxylase by phosphorylating conditions. Ca^{2+} concentrations were adjusted to the indicated values by the use of Ca^{2+}-EGTA buffers. Zero Ca^{2+} refers to the use of excess EGTA.

useful in identifying CaM dependent biological reactions and previous studies (*see* above) satisfied one criterion, Ca^{2+} dependency. A second criterion demands that the removal of CaM from the tissue alters the reaction. To test this, tegmental extracts were chromatographed on an affinity matrix comprised of fluphenazine covalently attached to Sepharose 4B (*see* Charbonneau & Cormier, 1979, for a description) in order to remove endogenous CaM. The data in the Table indicate that removal of CaM rendered the hydroxylase unresponsive to phosphorylating conditions. The ability of exogenously added CaM to reinstate the activation in chromatographed brain extracts is also demonstrated in the Table, and these data satisfy another criterion, that CaM can be added back into the system from which it was removed and at the same time restore function to the system. Analysis of brain extracts by SDS-polyacrylamide slab gel electrophoresis both before and after affinity chromatography on fluphenazine Sepharose confirmed that CaM was indeed present in the brain under study (satisfying the fourth criterion of Cheung 1980) and that the affinity chromatography was quite efficient and selective in removing CaM. These results are shown in Figure 2.

A fifth criterion states that fluphenazine should inhibit the CaM-dependent reaction and is based on the observation that fluphenazine and a large number of other antipsychotic drugs bind with high affinity to CaM in a Ca^{2+}-dependent fashion (*see* Weiss et al. 1980). To test this criterion, a number of antipsychotic drugs were added to the tryptophan hydroxylase reaction mixture in the presence of phosphorylating conditions. The effects of three such drugs are shown in Figure 3. It can be seen that increasing concentrations of fluphenazine, trifluoperazine, and cis-flupenthixol produced inhibition of the phosphorylation-induced activation of tryptophan hydroxylase. Other antipsychotics including penfluridol, pimozide, haloperidol, and chlorpromazine were also effective in this regard, the inhibitory potencies for the inhibition of the activation of tryptophan hydroxylase by these drugs agreed precisely with the order of potency of the binding of these drugs to CaM (Weiss et al. 1980). Since these drugs are by no means completely specific in their *in vitro* actions, additional studies were carried out to assess the extent to which their inhibitory properties were related to CaM binding. The

Phosphorylation Effects on Tryptophan Hydroxylase After Chromatography on Fluphenazine-Sepharose

		Assay Conditions	
Enzyme	Addition	Control	Phosphorylating
Control	-	5.21 ± 0.07	8.44 ± 0.40
Chromatographed	-	5.65 ± 0.21	5.72 ± 0.18
	Calmodulin	5.32 ± 0.04	9.22 ± 0.42
	Calmodulin + EGTA	5.20 ± 0.15	4.62 ± 0.19

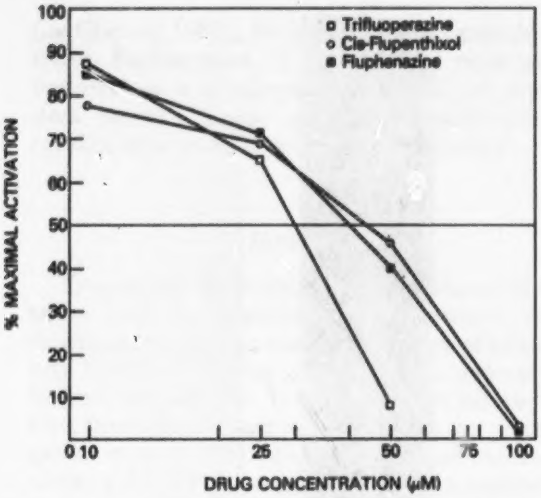

FIGURE 3. Drug-induced inhibition of the effects of phosphorylating conditions on tryptophan hydroxylase. Drugs were added in the final concentrations listed on the abscissa. Drugs used were: ■, fluphenazine; □, trifluoperazine; O, cis-flupenthixol. Data are expressed as percent maximal activation, calcualted by dividing the activity under phosphorylating conditions in the absence of drug. Reprinted, with permission, from Kuhn et al. 1980.

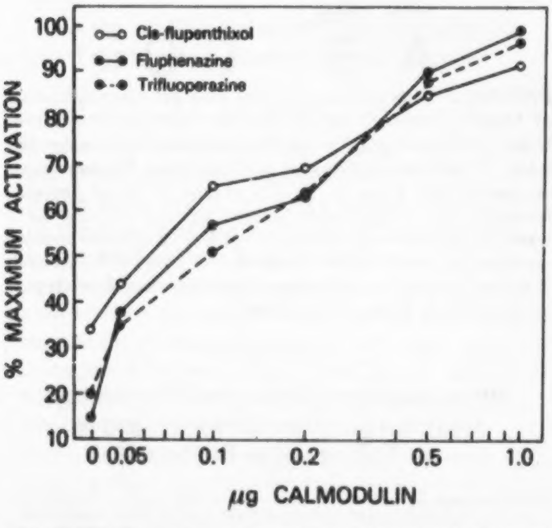

FIGURE 4. Protection against drug-induced inhibition of phosphorylation of tryptophan hydroxylase by calmodulin. Phosphorylation reaction mixtures were prepared and cis-flupenthixol (O-O), fluphenzaine (•—•) or trifluoperazine (•--•) was added to the reaction mixture. Reprinted, with permission, from Kuhn et al. (1980).

results in Figure 4 indicate that the addition of exogenous CaM to reaction mixtures containing fluphenazine, trifluoperazine, or cis-flupenthixol (50 μM for each) overcame the inhibitory effects of these drugs. Thus, it seems likely that the inhibitory effects of these drugs are mediated by their ability to bind to CaM.

A final criterion suggests that antibodies to CaM should prevent the CaM-dependent process but, unfortunately, this criterion has not yet been fulfilled. The assay for tryptophan hydroxylase requires the presence of a reducing agent, typically dithiothreitol (DTT), and DTT reduces the sulfhydryl bridge which retains structural integrity (and function) between the heavy and light chains of the IgG antibody raised against CaM. Experiments are continuing with various CaM antibody preparations to test their ability to block the CaM dependent activation of tryptophan hydroxylase.

In summary, the data suggest rather conclusively that CaM is an essential component in the activation of tryptophan hydroxylase by phosphorylating conditions. However, some very important questions have not yet been answered. For example, is tryptophan hydroxylase itself directly phosphorylated during activation or is some other protein intermediate the substrate for the CaM-dependent protein kinase? Only studies with highly purified preparations of tryptophan hydroxylase will allow this question to be answered and unfortunately, such a purified enzyme preparation is not yet available. Another question which must be answered is whether this phosphorylation-induced activation occurs *in vivo*. Fortunately, some data are available which are pertinent to this question. For example, tryptophan hydroxylase in brain slices is activated by neuronal depolarizing conditions in a Ca^{2+} dependent manner and this activation can be blocked by fluphenazine (Mestikevay et al. 1982; Boadle-Biber 1982). Furthermore, the cerebral distribution of the Ca^{2+} -CaM dependent protein kinase parallels that of tryptophan hydroxylase (Hamon et al. 1979), and selective destruction of 5-HT cells with the neurotoxin 5,7-dihydroxytryptamine also substantially reduces Ca^{2+} dependent protein kinase activity (Hamon et al. 1979). Finally, Yamauchi and Fujisawa (1980) have identified three different CaM-activated protein kinases in brain, and tryptophan hydroxylase is apparently a substrate for one of these enzymes. Although these data do not constitute conclusive proof, collectively they strongly indicate that a Ca^{2+}-CaM dependent protein kinase can phosphorylate tryptophan hydroxylase *in vivo,* and this mechanism could be closely coupled to neuronal depolarization and Ca^{2+} influx.

Control of Phosphorylation of a Vesicle-Associated Protein, Synapsin 1[1]

Mary B. Kennedy, Ph.D.[2]

Reversible phosphorylation of proteins, catalyzed by a class of enzymes called protein kinases, has been shown to play a role in regulating a variety of cellular processes. For example, several hormones stimulate the synthesis of cAMP which then acts as a "second messenger," stimulating the phosphorylation of specific proteins by cAMP-dependent protein kinase (Greengard 1978; Krebs & Beavo 1979). In an attempt to understand the mechanism of action of neurotransmitters that have relatively long term effects on neurons, Paul Greengard's laboratory showed that some of these neurotransmitters stimulate the synthesis of cAMP (Greengard 1981). More recently, the same lab has described a protein doublet, initially termed protein I, that is found only in neural tissue, and is phosphorylated by cAMP-dependent protein kinase (Ueda & Greengard 1977). Studies on the location of protein I have shown that it is located specifically in most, if not all, synaptic terminals (Bloom et al. 1979; DeCamilli et al. 1979) where it is associated primarily with synaptic vesicles (Ueda et al. 1979; DeCamilli, Harris, Huttner and Greengard, in preparation). Because of its location, the protein has been renamed synapsin I (Huttner et al. 1981a).

More detailed studies on phosphorylation of synapsin I have shown that its phosphorylation can be regulated by free calcium levels in nerve terminals, as well as by cAMP (Krueger et al. 1977). This was demonstrated in an experiment in which brain synaptosomes were prelabeled with ^{32}P-phosphate, then transferred to depolarizing solutions containing either veratridine or high potassium, in the presence or absence of calcium. Following brief incubations, protein phosphorylation was assessed by SDS gel electrophoresis and

autoradiography. Depolarization in the presence of calcium, but not in its absence, increased the rate of phosphorylation of synapsin I (Krueger et al. 1977; Sieghart et al. 1979). Three lines of evidence indicate that the calcium-stimulated phosphorylation occurs by a pathway distinct from the cAMP-dependent pathway. First, depolarization of synaptosomes in the presence of calcium produces no measurable increase in cAMP (Krueger et al. 1977). Second, calcium-stimulated phosphorylation occurs at three distinct sites on the synapsin I molecule. One (site 1) is recovered in a 10 kdalton fragment after proteolysis with *Staph aureus* V8 protease and is the same site that is phosphorylated by cAMP-dependent kinase. The other two (sites 2 and 3) are recovered in a 30 kdalton fragment and are not phosphorylated by cAMP-dependent protein kinase under physiological conditions (Huttner & Greengard 1979; Huttner et al. 1981b). Finally, calcium and calmodulin-dependent protein kinase activity has been identified in synaptosomal lysates (Schulman & Greengard 1978a,b).

In order to purify and characterize the calcium-dependent protein kinase or kinases that phosphorylate synapsin I, a quantitative assay for such kinases was developed using purified synapsin I as a substrate (Kennedy & Greengard 1981; Figure). Under optimal conditions in this assay, the rate of phosphorylation of synapsin I by a crude brain homogenate is stimulated as much as 40-fold by calcium ion to a rate of about 5 nmoles/min/mg of protein. Both the soluble and particulate fractions of the homogenate contain calcium-stimulated synapsin I kinase (Figure). The soluble activity catalyzes the phosphorylation of all three sites on synapsin I, while the particulate activity phosphorylates primarily sites 2 and 3 (Kennedy & Greengard 1981). Fractionation of the soluble proteins by DEAE-chromatography revealed the presence of two distinct synapsin I kinases. One peak of activity phosphorylated site 1 ("10 k fragment kinase") while the other, larger, peak phosphorylated sites 2 and 3 ("30 k fragment kinase"). The 10 k fragment kinase is calcium-dependent, but does not at this stage of purification require exogenous calmodulin. It is, however, inhibited by 50 μM trifluoperazine which suggests that it may be calmodulin-dependent, and have a sufficiently high affinity for calmodulin that the two copurify through the DEAE fractionation. The 30 k fragment kinase is both calcium and calmodulin-dependent.

FIGURE. The fractions of brain homogenate were prepared, and assays performed as described in Kennedy and Greengard, 1981.

This latter soluble synapsin I kinase activity is apparently closely related or identical to the particulate calmodulin-dependent synapsin I kinase (Kennedy, McGuinness, and Greengard, manuscript in preparation). Fifty to seventy percent of the particulate enzyme can be solubilized by prolonged incubation in dilute buffer, and can then be partially purified by DEAE-cellulose chromatography. The enzymes of both soluble and particulate origin have been further purified by calmodulin-sepharose affinity chromatography. At this stage of purification, the two enzymes are indistinguishable in their catalytic properties (substrate specificities, affinity for substrates, calcium requirement, optimum pH) and in their mobilities on DEAE-cellulose.

Both of the brain synapsin I kinases can be distinguished from the two previously described calmodulin-dependent protein kinases, myosin light chain kinase (Dabrowska et al. 1978; Yagi et al. 1978) and phosphorylase kinase (Cohen et al. 1978), by differences in their substrate specificities (*see* Table), in their mobilities on DEAE-cellulose, and in their tissue distributions

(Kennedy & Greengard 1981). The calcium-stimulated synapsin I kinase activities are three to ten times more highly concentrated in brain homogenates than in any other tissue homogenates assayed. The relationship of these enzymes to the endogenous particulate calmodulin-dependent protein kinase described by Schulman and Greengard is being investigated.

Table

Comparison of Substrate Specificities of Calmodulin-Dependent Protein Kinases

	Substrate		
Enzyme	Myosin Light Chain	Phosphorylase b	Synapsin I
	pmole/min	pmole/min	pmole/min
Myosin light chain kinase (M. Conti and R. Adelstein)	27	---	5.7 (10 k fragment)
Phosphorylase kinase (J. Wang)	---	14	1.3 (30 k fragment)
Crude synapsin I kinase 1.		<0.02	76
2.	0.08		89

Purified enzymes were obtained from the indicated investigators. Crude synapsin I kinase refers to the DEAE peak of enzyme activity described in Kennedy and Greengard, 1981. Myosin light chain was a gift of Dr. Angus Nairn. Phosphorylase b was purchased from Sigma Chemical Co. Assays were performed as described in Kennedy and Greengard, 1981. Mixing experiments indicated that the crude synapsin I kinase preparation did not contain substances that interferred with the measurement of either myosin light chain kinase or phosphorylase kinase.

The complex regulation of phosphorylation of synapsin I, together with its association with synaptic vesicles, suggests it is involved in a vesicle function that is regulated by events that alter either cyclic AMP levels or calcium levels. One such function is transmitter release. In some terminals, agents that alter cyclic AMP levels can cause facilitation, which is an increase in the number of quanta of transmitter released per impulse (e.g., Goldberg & Singer 1969; Kandel 1981). In addition, under some circumstances, calcium influx through voltage-dependent calcium channels can lead to post-tetanic potentiation which is a relatively long-lasting increase in the number of quanta released per impulse (Rosenthal 1969). Future experiments should elucidate whether synapsin I is involved in regulation of transmitter release, or in some other vesicle function.

Acknowledgment: The help of C. Hochenedel in preparing this manuscript is greatefully acknowledged.

Action of Hallucinogenic Drugs at Postsynaptic Serotonergic Receptors[1]

Barry L. Jacobs, Ph.D.,[2] James Heym, Ph.D.,[2] and Kurt Rasmussen, B.S.[2]

Hallucinogenic drugs such as LSD, psilocin, 2,5-dimethoxy-4-methylamphetamine (DOM), mescaline, and N,N-dimethyltryptamine (DMT) appear to constitute a distinct drug class based on their similar phenomenological effects in humans and the fact that cross-tolerance can be demonstrated between many of them. Theories regarding the mechanism of action of these drugs have gone through several distinct phases, all of them focusing on the role of serotonin. In the initial phase, in the mid-1950s, LSD was hypothesized to exert its psychological actions by blocking serotonin's synaptic effect. These conclusions, however, were based exclusively on pharmacological studies of LSD's action in the periphery, and were soon criticized. Following this, in the early 1960s, the emphasis shifted to an effect upon serotonin in the central nervous system (CNS), but without regard to the precise site of action, i.e., presynaptic or postsynaptic. In the mid-1960s, studies employing fluorescence histochemistry delineated the localization of serotonin-containing neurons within the CNS, their projection pathways, and their axon terminal distribution. This information provided the foundation for theories in the 1970s which proposed that the effects of LSD and related hallucinogens were mediated specifically by an action upon the cell bodies of serotonergic neurons (hereafter referred to as the "presynaptic" effect). Finally, in the fourth phase, emphasis has switched to the action of hallucinogenic drugs directly upon the target neurons of serotonergic projections (hereafter referred to as the "postsynaptic" effect). The data supporting this latest concept, which have been gathered primarily within the last few years, will be the subject of this brief review. Because of space limitations, many of the issues discussed will be either minimally referenced or unreferenced. For more detailed information, the reader is referred to two recent reviews (Jacobs & Trulson 1981; Jacobs, in press).

[2] Program in Neuroscience, Department of Psychology, Princeton University, Princeton, NJ 08544.

The authors will first describe the presynaptic model. This will provide a more meaningful and appropriate context in which to discuss the postsynaptic model, as well as afford the opportunity to compare and contrast the two models.

Based on previous neurochemical data which indicated that LSD decreased serotonin turnover, Aghajanian and his co-workers reasoned that this might be mediated by a decrease in the unit activity of serotonergic neurons. They therefore set out to test this directly be examining the effects of systemic administration of LSD on unit activity of brain serotonergic neurons in the chloral hydrate anesthetized rat (Aghajanian et al. 1968). They lowered tungsten microelectrodes into the brain area with the densest aggregation of serotonergic neurons, the midbrain dorsal and median raphe nuclei, and observed the slow (1-2 spikes/sec) and regular discharge pattern that appears to characterize all serotonergic neurons in brain. When LSD was then administered intravenously, a dose of 25-50 μg/kg was sufficient to cause a complete suppression of activity. By contrast, none of the neurons outside of the raphe ceased firing in response to the drug. An important control experiment in this series demonstrated that, unlike LSD, brom-LSD exerted virtually no effect on serotonergic neurons in doses of 25-50 μg/kg. These same investigators went on to test the effects of a variety of systemically administered psychoactive drugs, including several hallucinogens (Aghajanian et al. 1970). They reported that DMT produced an effect very similar to that of LSD, but at significantly higher doses (approximately 700 μg/kg). Interestingly, mescaline and DOM depressed the activity of only a subgroup of midbrain raphe neurons, those in the ventral portion of the dorsal nucleus. Atropine, scopolamine, phencyclidine, and chlorpromazine were essentially without effect on serotonergic unit activity. In separate studies, Aghajanian's group also showed that psilocin was effective in depressing serotonergic unit activity, whereas amphetamine consistently increased the activity of these cells. Finally, an experiment from the authors' laboratory indicated that low doses (20 μg/kg, i.v.) of the hallucinogen 5MeODMT also exerted a potent depressant effect on the activity of serotonergic neurons (Mosko & Jacobs 1977).

The next issue was to determine whether LSD and related hallucinogens exerted their depressant effects directly on serotonergic neurons, or whether this action was mediated indirectly, perhaps by some type of feedback loop. The most straightforward approach to this question involved the direct application of LSD, psilocin, DMT, 5MeODMT, and mescaline onto neurons in the area of the dorsal raphe nucleus by means of microiontophoresis. In all cases, excluding those experiments with mescaline, the iontophoretic application of the hallucinogenic drugs produced a profound suppression of serotonergic unit activity at low ejection currents (Haigler & Aghajanian 1973; Aghajanian & Haigler 1975). This supported the hypothesis that the effect of hallucinogenic drugs is mediated by a direct action upon serotonergic neurons, possibly one mediated by serotonin receptors. Since the iontophoretic application of mescaline failed to depress serotonergic unit activity, even in the subset of those cells that were affected by systemic administration, it was concluded that unlike the other hallucinogens, mescaline's effect on serotonergic neurons is mediated indirectly.

A final, very important issue remained to be resolved. If the action of hallucinogenic drugs is mediated by a depressant action on serotonin-containing neurons, why then are not compounds such as l-5-hydroxytryptophan (5-HTP) and l-tryptophan, both of which depress raphe unit activity, hallucinogenic? The answer, at least in the context of this theoretical framework, is contained in two elegant experiments by Haigler and Aghajanian (1973, 1974). When serotonin is iontophoretically applied onto serotonergic neurons in the raphe nuclei and onto their postsynaptic target neurons in the ventral lateral geniculate or amygdala, it is approximately equipotent in depressing unit activity at these various sites. Contrary to this, when LSD or psilocin is tested in the same manner, it has a much more profound effect on the serotonergic cells than on their target neurons. In other words, hallucinogenic drugs have an action that appears to be *preferential* for serotonin-containing neurons. Thus, it is reasoned, when brain levels of serotonin are elevated by administration of its precursors 1-5-HTP or l-tryptophan (or any of a variety of other pharmacologic means), serotonergic unit activity is depressed, but so is the activity of target neurons receiving serotonergic inputs. On the other hand, when LSD is administered systemically, it acts to depress serotonergic unit activity, while having little direct effect on target neurons. Because much of serotonin's action on target neurons in the forebrain is inhibitory, it is hypothesized that the ultimate effect of LSD's preferentially depressant action on serotonergic neurons is to produce a disinhibition of target neurons, which is precisely the opposite of the depression produced by elevated synaptic levels of serotonin.

Since this disinhibition will be manifested most impressively in those areas with the densest aggregation of serotonin axon terminals, i.e., portions of the visual system and limbic system, an obvious neuronal model is available to account for two of the major aspects of hallucinogenic drug action: visual hallucinations and alterations of affect. This, then, is the presynaptic serotonergic model of hallucinogenic drug action. It is based on several assumptions: 1) All hallucinogenic drugs strongly depress the activity of at least some group of serotonergic neurons. 2) Serotonin's synaptic action in the forebrain is strictly inhibitory. 3) Hallucinogenic drugs exert little direct effect on postsynaptic serotonergic receptors. There is now reason to question the validity of all three of these assumptions, however, in this review, focus will be on only the first and the third.

All of the electrophysiological studies described above were conducted in anesthetized and/or immobilized animals, thus making it impossible to relate changes in unit activity produced by hallucinogenic drugs to changes in behavior. If our ultimate goal is to draw conclusions about functional relationships, such analyses are imperative. In an attempt to provide a more stringent test of the presynaptic model of hallucinogenic drug action, the authors decided to administer these drugs to awake freely moving cats and to study changes in the activity of brain serotonergic neurons concomitantly with changes in behavior. In order to analyze the behavioral effects of the hallucinogens, they employed an observational method of scoring changes in the spontaneous occurrence of specific response categories in the cat (Jacobs et al. 1977). In order to record the activity of single units in freely moving cats, they developed a technique that employs bundles of flexible large-tipped microwires (32 or 64 μm diam.) rather than the traditional small-tipped high-impedance metal or glass microelectrodes (Jacobs et al. in press). These bundles of microwires can be advanced through the brain by means of an attached mechanical microdrive. Using this technique, the authors had great success in isolating serotonergic units in various raphe nuclei of the cat brainstem (e.g., dorsalis, centralis superior, and pallidus). This technique also allows them to "hold" cells for long periods of time (from several hours up to several days) and in spite of vigorous movements on the part of the cat.

The authors first describe their experiments with 5-MeODMT, which has a molecularly more simple structure than LSD and produced more clearcut data. They were particularly interested in the temporal correlations between the onset, peak, and offset of the behavioral and unit data, and whether or not the behavioral and unit data would have a correlated dose dependency. In order to examine these issues, they administered 5-MeODMT in doses of 10, 25, 50, 100, or 250 μg/kg intramuscular (i.m.) and monitored the activity of serotonin-containing neurons in the dorsal raphe nucleus in conjunction with any gross behavioral effects (Trulson & Jacobs 1979a). Under baseline conditions, serotonergic neurons in the awake freely moving cat discharge with the same characteristic slow rhythmic activity seen in the anesthetized rat. Following injections of 5-MeODMT, serotonergic unit activity was rapidly depressed in a dose-dependent manner, and dose-dependent increases were observed in the rate of limb flicking and abortive grooming. Furthermore, the onset, peak, and offset of the behavioral effects were temporally correlated with the onset, peak, and offset of changes in unit activity. By directly correlating behavioral changes with changes in the activity of serotonin-containing neurons, the authors at the time, felt that this study provided perhaps the strongest direct evidence for the presynaptic serotonin hypothesis of hallucinogenic drug action.

When this approach was extended to the study of LSD, the results were generally similar to those seen with 5-MeODMT, but with two critical differences (Trulson & Jacobs 1979b). First, a 50 μg/kg dose of LSD produced a depression of serotonergic unit activity lasting, on the average, 3-4 hours, while the behavioral effects lasted for at least 6-8 hours. Second, when the 50 μg/kg dose was readministered 24 hours later, it produced little or no behavioral effect (tolerance), but the effect on serotonergic unit activity was as large as two dissociations of unit activity and behavior, the authors began to question the validity of the presynaptic serotonergic hypothesis.

This skepticism has been bolstered by their more recent experiments with DOM, mescaline, and psilocin (Trulson et al. 1981). With all three drugs, they observed the same temporal dissociations of serotonergic unit activity and behavior as observed with LSD. In addition, a low dose of psilocin (25 μg/kg, i.p.) produced no significant decrease in serotonergic unit activity in any of the cells tested, however, it did produce significant behavioral effects. Mescaline (5 mg/kg, i.p.) produced no overall significant change in unit activity (the discharge of three cells increased, three decreased, and two showed no change), but did produce large behavioral effects. Similarly, a low dose of DOM (50 μg/kg, i.p.) did not significantly affect any of the serotonergic units tested, but did have a significant behavioral effect. The highest dose of DOM (1 mg/kg), produced only increases in serotonergic unit activity, but nonetheless elicited significant behavioral changes. Furthermore, cells in the ventral portion of the dorsal raphe nucleus did not apoear to be preferentially sensitive to either mescaline or DOM. Finally, although not extensively examined, the authors observed similar results, with various hallucinogens, in experiments on serotonergic neurons in nucleus centralis superior (Rasmussen, Heym, and Jacobs, unpublished observations).

Also examined were the effects of LSD upon unit activity of neurons in nucleus raphe pallidus, the most caudal group of serotonergic neurons in the cat brainstem. Somewhat surprisingly, the majority of neurons examined were almost completely unresponsive to doses of LSD (50 μg/kg, i.p.) and 5-MeODMT (50 μg/kg, i.m.) that produced potent behavioral effects (Heym, Steinfels, and Jacobs, submitted for publication).

The authors most recent study in this series provided perhaps the most damaging evidence to the presynaptic serotonergic hypothesis of hallucinogenic drug action, and began to focus their attention on the postsynaptic actions of these drugs. When cats were administered mianserin (0.1-1.0 mg/kg, i.p.), a serotonin postsynaptic antagonist, 30 minutes prior to LSD (50 μg/kg) or DOM (250 μg/kg), it blocked their behavioral effects in a dose-dependent manner. This did not appear to be due to nonspecific effects, since the drug produced no decrease in spontaneous activity and the animals did not appear to be sedated or cataleptic. Furthermore, mianserin exerted no blocking action on the behavioral effects of the dopamine agonist apomorphine. When animals were pretreated with mianserin (1 mg/kg, i.p.) and then administered LSD (50 μg/kg, i.p.) 30 minutes later, an almost complete blockade of the behavioral effects of LSD was observed, but no alteration of the 40-60 percent depression of serotonergic unit activity that LSD typically produces in neurons in nucleus raphe dorsalis and centralis superior (Heym, Rasmussen, and Jacobs, unpublished observations).

There are a number of other reasons for emphasizing the behavioral importance of the direct serotonergic postsynaptic effects of hallucinogenic drugs. However, space limitations will allow only a brief description of each of them.

1. Administration of a number of different hallucinogens produces behavioral effects indicative of a direct serotonergic agonist action at postsynaptic receptor sites. This is the elicitation of the so-called "serotonin syndrome" (Jacobs 1976). Evidence that this is a direct action is provided by studies which show that the effect is not blocked by prior serotonin depletion. Repeated administration of LSD diminishes its behavioral potency (tolerance) (Trulson et al. 1976). This is unaccompanied by a change in sensitivity of serotonergic neurons to LSD, but is accompanied by a decrease in the number of available serotonergic postsynaptic receptor binding sites (Trulson & Jacobs 1979c).

2. Studies in a variety of different species, including humans, demonstrated that prior depletion of serotonin enhances the behavioral effects of hallucinogenic drugs. In many of these cases there is direct evidence for the presence of serotonergic postsynaptic supersensitivity at the time the hallucinogens are administered.

3. In a variety of different paradigms, including drug discrimination, operant responding, and spontaneous behavior, the behavioral effects, in rat, of a number of hallucinogens can be effectively blocked by several different serotonin antagonist drugs.

4. Chronic administration of a monoamine oxidase inhibitor (MAOI) for 1 or 2 weeks can totally block the behavioral effects of LSD and other hallucinogens in rat, cat, and humans. This blocking action may persist for as long as 2 weeks

following withdrawal from the MAOI. Neurochemical evidence strongly indicates that this decreased response to hallucinogenic drugs is mediated by a decrease in the availability of postsynaptic binding sites for serotonin.

5. Binding of [^{3}H]-LSD, whether examined autoradiographically or using receptor specific binding assays, is unchanged by destruction of serotonergic neurons. Since much of this binding can be displaced with serotonin, it indicates that it is associated with serotonin receptors but, apparently, not those localized on various aspects of the presynaptic neuron.

In summary, it is well-known that hallucinogens, such as LSD, psilocin, mescaline, DMT and DOM, produce similar effects in humans and also display cross-tolerance of action. The most parsimonious explanation for these similarities is that these drugs share, at least to some extent, a common biological action. Evidence from a variety of disciplines, some of which was reviewed here, indicates that this common action is exerted upon the brain serotonin system. (Although various hallucinogens may interact with neurotransmitter systems other than serotonin, they do not do so universally.) It may be useful at this point to review what is known regarding the synaptic interactions between the hallucinogens and serotonin. Hallucinogens produce: 1) depression of the activity of serotonergic neurons (the so-called presynaptic action); 2) a modest inhibitory action at serotonin postsynaptic receptor sites in the forebrain, especially subcortically; 3) a strong antagonist action to serotonin's excitatory effects on its postsynaptic target sites in a variety of brain areas, especially in cerebral cortex and brainstem; and 4) a potentiation (or facilitation) of the facilitatory effect exerted by serotonin on excitatory inputs to its target sites in the brainstem and spinal cord. Thus, the interactions of the hallucinogens with the brain serotonin system are complex, with mixed agonist, antagonist, and modulatory effects. As argued above, however, the critical effect is probably exerted directly upon cells postsynaptic to brain serotonin-containing neurons.

Interaction of Monoamine Blocking Agents with Behavioral Effects of N,N-Dimethyltryptamine

David M. Stoff,[1,3] **Dilip V. Jeste, M.D.,**[1]
Egidio A. Moja, M.D.,[2] **Ken A. Stauderman,**[1]
and Richard J. Wyatt, M.D.[1]

Among the methylated hallucinogenic indoleamines, N,N-dimethyltryptamine (DMT) has been the most extensively studied concerning its possible role in schizophrenia (Gillin et al. 1976, 1978). Since the 5-hydroxytryptamine (5-HT) deficiency hypothesis for LSD was first proposed in the early 1950s, an impressive body of neurochemical and electrophysiological evidence has accumulated suggesting that DMT (and other indole hallucinogens) acts via interference of central 5-HT neurotransmission (Jacobs & Trulson 1981). In addition to possessing a serotonergic component, DMT may exert some of its effects by acting on other interrelated neurotransmitter systems. While there are a large number of studies demonstrating an interaction between drugs affecting the major monoamines (serotonin, dopamine, norepinephrine) in brain and some of the behavioral effects of other hallucinogens (Wyatt et al. 1976), similar data for DMT are sparse and conflicting. The human data are consistent with a 5-HT deficiency hypothesis since the monoamine oxidase inhibitor (MAOI), iproniazid, attenuated the psychological effects of DMT (Sai-Halasz 1963) while the serotonin receptor antagonists (2-bromo-LSD, methysergide) potentiated its effects (Sai-Halasz 1962). However, different results have been reported in animals where MAOIs potentiate some autonomic and behavioral effects caused by DMT (Moore et al. 1975; Vasko et al. 1974) while DMT-induced behavioral effects are antagonized, potentiated, or unaffected by different 5-HT receptor blockers (Corne & Pickering 1967; Jenner et al. 1980; Kovacic et al. 1978; Smythies et al. 1972; Winter 1972). Although neuroleptics block some behavioral effects of DMT (Jenner et al. 1980; Quock et al. 1979; Shah & Hedder 1978), similar blockade occurs among structurally unrelated hallucinogens and even these effects can be attributed to a behaviorally depressant action of the neuroleptic itself.

The authors previously reported DMT-induced disruption of rat shuttlebox avoidance (Stoff et al. 1977), an effect that occurs under conditions where the 5-HT behavioral syndrome was not observed. Here, they present a detailed series of dose response studies showing that various monoamine blocking agents (dopaminergic: chlorpromazine, clozapine, haloperidol, pimozide, thioridazine, noradrenergic: phenoxybenzamine, propranolol; serotonergic: cinanserin, cyproheptadine, methiothepin, methysergide) were unable to influence the DMT effect, at doses which by themselves did not alter avoidance behavior; as expected, pargyline potentiated DMT (*see* Table). Furthermore, DMT-induced disruption was uninfluenced by chronic neuroleptic treatment and pretreatments with 1) 1-methyl-1, 2, 5, 6-tetrahydropyridine-3-(N-, N-diethylcarboxamide) hypothesized to act at the site of action for DMT (Smythies et al. 1972); 2) BC-105, which blocks some behavioral effects of the close chemical relative, 5-methoxy-DMT (Winter 1978); or 3) alpha-methyl-para-tyrosine (AMPT). Some of the antagonists employed have more than one pharmacological action and little, if anything, is known about the ability of these compounds to interact with the site of action of DMT.

The authors' results may be consistent with the action of DMT through systems besides the major monoamines. Other data suggest the involvement of tryptamine receptors in the action of LSD and similar compounds (Martin et al. 1978) and tryptamine, the proposed biosynthetic precursor of DMT, causes similar effects to DMT in the same animal model (Vogel & Cohen 1977). More recently, an involvement of the opioids has been suggested since DMT-induced bar press disruption was antagonized by morphine and methadone and potentiated by naloxone (Ruffing & Domino 1981; Ruffing et al. 1979). The role of these and other putative neurotransmitter and peptide systems in the action of DMT deserves further attention.

Evidence for Opioids as Partial Antagonists for Indole Hallucinogens

Edward F. Domino, M.D.,[1, 2] **and Diane M. Ruffing,**[2]

Various observations have supported the hypothesis that endogenous opioid peptides are involved in psychoses either therapeutically or pathogenically (Rimón et al. 1980; Pickar et al. 1981). Prior to the advent of neuroleptics, opioids such as morphine were used historically to treat mental disease. Hence, the role of opioids in psychoses is obscure and complex. It was decided to use an animal model of drug-induced psychotic behavior to investigate this interaction further (Ruffing et al. 1979; Ruffing & Domino 1981). Several opioid agonists, antagonists, and synthetic enkephalin analogues were studied on N,N-dimethyltryptamine (DMT) and lysergic acid diethylamide (LSD-25) induced disruption of food-rewarded FR_4 bar-pressing behavior in the rat. The striking interactions observed are reported herein.

Method

Adult male Holtzman rats were maintained at 70 percent of their expected free-feeding weight. Stable food-rewarded fixed ratio 4 (FR_4) bar pressing behavior was established, followed by daily 60-minute bar pressing sessions for a minimum of days prior to injections. Animals were then randomly assigned to groups ($N = 5$-12), scheduling each rat to serve as its own control to compare hallucinogen-induced effects with and without assigned pretreatment drugs. Control groups were pretreated with 0.9 percent NaCl intraperitoneally (i.p.) prior to DMT (3.2-10.0 mg/kg) and LSD (0.1 mg/kg) injections. A minimum 7-day drug-free interval was observed between scheduled injections. Predetermined behaviorally noneffective pretreatment drug doses given 10-20 minutes prior to DMT or LSD were as follows: morphine sulfate and methadone hydrochloride (0.32-3.2 mg/kg), (+)-MR 2267 (5.6-10.0 mg/kg), (−)-MR 2266 (3.2 mg/kg), (+)-naloxone hydrochloride (3.2 mg/kg), (−)-naloxone hydrochloride (1.0-3.2 mg/kg), naltrexone (1.16-3.7 mg/kg), (+)- and (−)-WIN 44,441-2/3 enantiomers (1.47-3.52 mg/kg), Lilly 127623 (0.0032-0.32 mg/kg), and FK 33-824(0.0001-0.01 mg/kg). All drug dosages refer to free base and were administered i.p. Two-tailed Student's *t*-test paired comparison determinations, calculated according to Snedecor (1956), were used to analyze pretreatment and/or hallucinogen drug effect interactions (i.e., antagonism, potentiation, or no effect). Due to the limited quantity of (+)-naloxone HCl and (−)-MR 2266, incomplete dose-effect relations are reported.

Results

DMT (3.2-10.0 mg/kg) and LSD (0.1 mg/kg) induced a reproducible disruption of food-rewarded bar pressing. Characteristic DMT and LSD-induced gross behavioral effects (evident within 2-5 minutes following i.p. injections) consisted of: lying quietly with the eyes open in an excessively flattened position for prolonged intervals, periodic Straub tail, muscular twitching and/or body movements, circling in a flattened position or reverse crawling, splayed and/or extension of the hind limbs, periodic stereotypic repetitious body movements, sustained periods of arching, and disinterest in food and/or bar pressing. The DMT and LSD-induced gross behavioral effects described above or with pretreatment drugs were consistent in all groups tested excepting morphine, methadone, and (−)-MR 2266 pretreated groups. In the morphine pretreated animals fewer and less intense gross behavioral effects were observed with periodic interest in food and/or bar pressing. Paradoxically, intensified gross behavioral effects were observed in the methadone and (−)-MR 2266 pretreated groups (i.e., increased and excessive flattening with frequent sustained repetitious head/body movements and markedly increased Straub tail). At the cessation of drug effects the rats would appear normal and abruptly start and continue bar pressing at pre-injection response rates.

The opioid agonist pretreatment groups (Figure 1) showed selective biphasic effects, i.e., morphine (0.32-1.0 mg/kg) and methadone (0.32 mg/kg) antagonized the effects of DMT and LSD-induced bar pressing disruption, whereas larger doses of morphine (3.2 mg/kg) and methadone

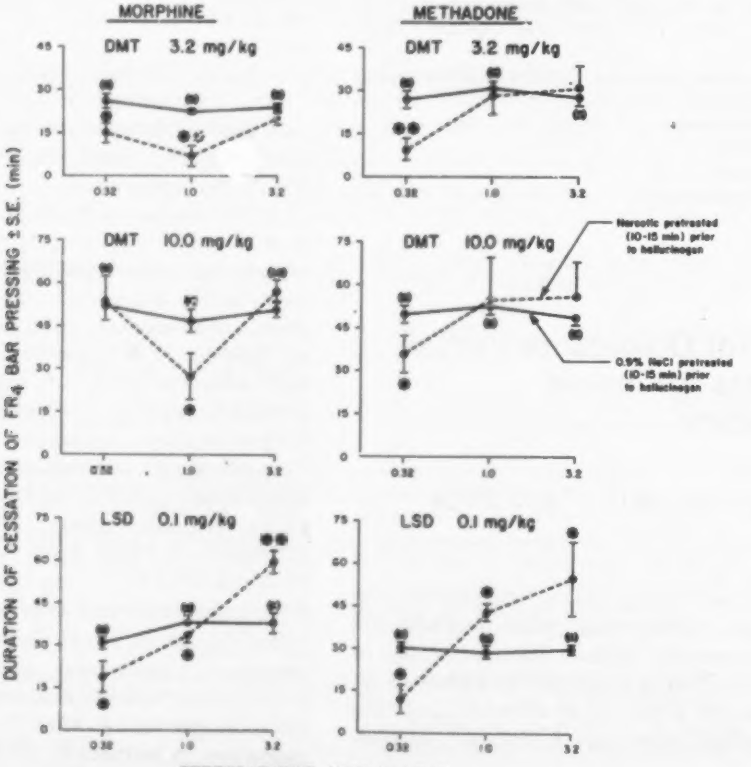

FIGURE 1. Effects of morphine and methadone pretreatment on DMT and LSD-induced disruption of FR_4 bar pressing behavior in the rat.

(1.0-3.2 mg/kg) selectively potentiated only LSD-induced effects with no differences noted in the DMT groups. The data indicate morphine as the more effective antagonist for DMT (3.2 mg/kg) and LSD-induced activity.

Conversely, the opioid antagonists, naloxone and naltrexone in pretreatment doses of 1.0-3.2 and 1.16-3.7 mg/kg, respectively, potentiated the behavioral DMT and LSD-induced effects as shown in Figure 2. Potentiation of DMT-induced effects was attributed to a stereospecific opioid antagonist effect of (−)-naloxone in that the (+)-naloxone enantiomer failed to interact or potentiate DMT (Ruffing & Domino 1981).

Pretreatment with stereo-isomers of two selected synthetic opioid antagonists, (+)-WIN 44,441-2, (−)-WIN 44,441-3, (+)-MR 2267, and (−)-MR 2266, unexpectedly demonstrated no interaction with DMT (3.2 mg/kg) induced disruption of FR_4 behavior, whereas both (+)- and (−)-WIN 44,441 enantiomers selectively potentiated the behavioral induced LSD effects, while only the (−)-MR 2266 stereo-isomer selectively antagonized behaviorally induced LSD effects (Figure 3).

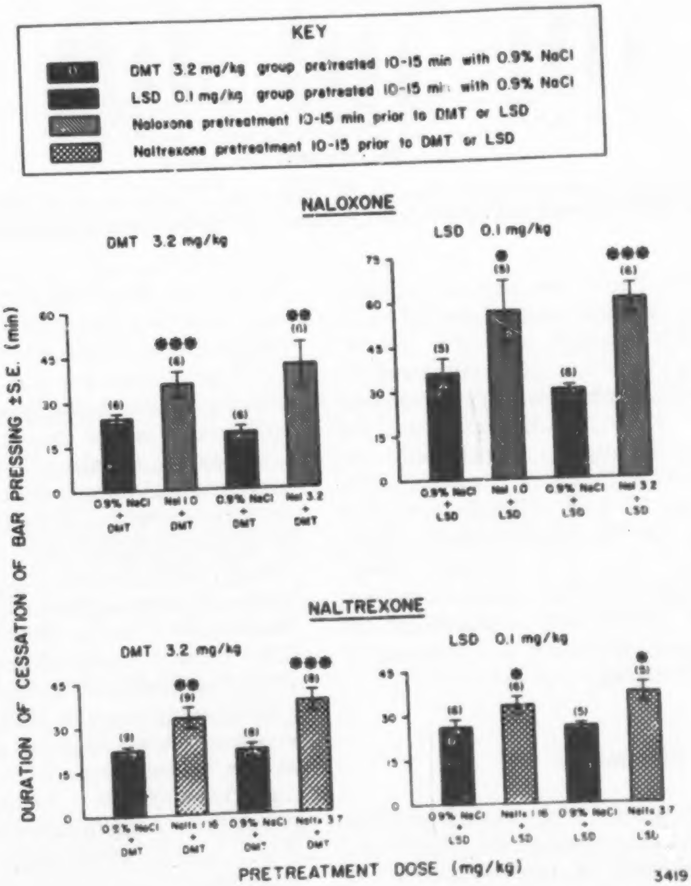

FIGURE 2. Potentiation of DMT and LSD-induced disruption of FR_4 bar pressing behavior in rats pretreated with naloxone and naltrexone.

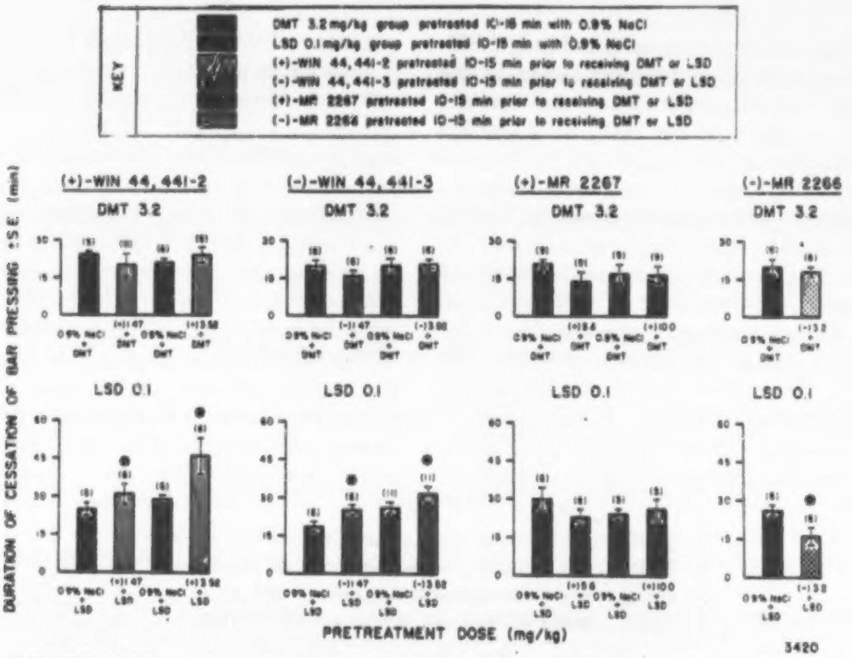

FIGURE 3. Effects of pretreatment with WIN 44,441-2, WIN 44,441-3, MR 2266, and MR 2267 on DMT and LSD-induced disruption of FR$_4$ bar pressing behavior in the rat.

As shown in the Table, the peptide synthetic enkephalinanalog pretreatment doses of Lilly 127623 (0.01-0.32 mg/kg) and FK 33-824 (0.001-0.01 mg/kg) significantly antagonized the effects of DMT (3.2 mg/kg), while pretreatment doses of Lilly 127623 (0.10-0.32 mg/kg) and FK 33-824 (0.00032-0.01 mg/kg) significantly antagonized the effects of DMT (3.2 mg/kg), while pretreatment doses of Lilly 127623 (0.10-0.32 mg/kg) and FK 33-824 (0.00032-0.01 mg/kg significantly antagonized LSD-induced effects. Additionally, Lilly 127623 (0.032 mg/kg) pretreatment also significantly antagonized the behaviorally induced disruptive bar pressing effects of DMT 10.0 mg/kg.

Discussion

The results of the present study extend previous observations that naloxone potentiated DMT and LSD-induced disruption of food-rewarded bar pressing in the rat (Ruffing et al. 1979). It is generally known that the biologically active narcotic antagonist is the (−)-naloxone isomer. Thus, it is of special interest that (+)-naloxone was inactive in potentiating the effects of DMT, confirming stereospecificity.

There is evidence that DMT and LSD, while sharing similar hallucinogenic effects, also show differences in the extent of dopaminergic and serotonergic agonist effects. For example, LSD has been shown to produce potent dopaminergic activity not produced by DMT (Nichols 1981). It is also abundantly clear that there are multiple neurotransmitter and opioid receptors, so that many of these agents differ in their molecular mechanism of action (Snyder & Goodman 1980). The present study indicates that the various opioid agonists and antagonists have very complex interactions with DMT and LSD. Although no simple theory explains all of the data obtained in this investigation, the present study indicates that there are very important interactions between these hallucinogens and opioids in the rat. The dramatic antagonistic effects of the opioid peptides, Lilly 127623 and FK 33-824, are especially prominent and deserve additional investigation with various behavioral paradigms in different species of animals including man.

In Vitro Models to Examine Regulation of Transmitter Content and Adenylatecyclase Coupled Receptors in Neurons[1]

David C. U'Prichard, Ph.D.,[2,3] Karen M. Braas, B.S.,[2] and Deborah J. Kahn, B.S.[2]

Major psychoactive drug classes such as antidepressants and neuroleptics are now believed to exert their therapeutic effects by inducing long-term changes in receptor function at brain monoamine synapses. Chronic antidepressant treatment of rats, for example, causes a reduction in brain β_1-adrenergic receptor number and a down-regulation of both the proximal biochemical response, stimulation of adenylate cyclase activity (Wolfe et al. 1978; Moyer et al. 1981), and electrophysiological responses of neurons associated with β-receptor activation (Schultz et al. 1981). However, with other brain monoamine receptors there are apparent discrepancies between the effects of antidepressant treatment on receptor number obtained from binding studies, and receptor-mediated responses. Thus antidepressant treatment down-regulates the number of brain serotonin-2 (S2) receptors measured with ^{3}H-spiroperidol (Peroutka & Snyder 1980a, 1980b), but appears to cause serotonin receptor supersensitivity in electrophysiological experiments (de Montigny & Aghajanian 1978).

Similarly, although antidepressant treatment causes a functional subsensitivity of brain and peripheral α_2-adrenergic receptors (Crews & Smith 1980; McMillen et al. 1980), studies examining changes in binding of the agonist ligands ^{3}H-clonidine (CLO) and ^{3}H-*p*-aminoclonidine (PAC) to brain α_2-receptors have produced conflicting results, with antidepressant treatment reducing the B_{max} of ^{3}H-CLO in rat brain regions other than cortex (Smith et al. 1981) and clinically in human platelets (Garcia-Sevilla et al. 1981), while other laboratories, including the present investigators, observed that in rats, abbreviated (3 days) treatment with desmethylimipramine or iprindole increased the B_{max} of ^{3}H-PAC or ^{3}H-CLO (Reisine et al. 1980; Johnson et al. 1980). The investigators have also found that chronic immobilization stress down- regulates β-receptors in different rat brain regions, but causes an increase in the B_{max} of ^{3}H-CLO in cortex, and a decrease in the B_{max} of ^{3}H-CLO in other brain areas (U'Prichard & Kvetnansky 1980).

The investigators attempted to reconcile these differences between drug-induced binding and functional changes by investigating the mechanisms of monoamine receptor down-regulation as a result of chronic agonist exposure in cloned neural cells in culture. In particular, they were interested in comparing the mechanisms of down-regulation of receptors that stimulate adenylate cyclase (positively coupled), and of receptors that inhibit adenylate cyclase (negatively coupled). Among the former class are β-adrenergic, dopamine D1, and serotonin S1 receptors, while the latter class includes α_2-adrenergic and dopamine D2 receptors. S2 receptors show GTP-sensitivity (Hamon et al. 1980), and may turn out also to be negatively coupled to adenylate cyclase. Receptors of either class occur in two or more affinity states, mainly differentiated with respect to agonists, referred to as H (high) and L (low). Guanine nucleotides shift equilibrium between H and L states in favor of L, and so promote coupling of either type of receptor with adenylate cyclase (Hoffman & Lefkowitz 1980). An important corollary to this model is that whereas the B_{max} of an antagonist radioligand is likely to be a true indicator of total receptor density, the apparent B_{max} of an agonist ligand, measured over restricted ligand concentrations, will be more an index of the number of H states of the receptor rather than of total receptor density, and changes in the B_{max} of agonist ligands may indicate a shift in the equilibrium between H and L states, and thus altered receptor-effector coupling, rather than a change in receptor number.

A number of laboratories have examined the molecular characteristics of β-receptor down-regulation in cultured neural cells. Su et al. (1980) have analyzed the consequences of exposure of 1321N1 human astrocytoma cells to the β-agonist isoproterenol. Through combined measurements of binding and cyclase response, they determined that 1321N1 β-receptors are down-regulated in two phases, the first being an uncoupling of receptors from adenylate cyclase, with a shift from H to L forms of the receptors, but no change in total receptor population, followed by a second long-term phase of loss of receptor number.

The investigators have examined regulation of the negatively coupled α_2-receptor on cultured neuroblastoma x glioma NG108-15 hybrid cells. These cells are cholinergic in nature, synthesize and release acetylcholine, and contain negatively coupled α_2-adrenergic, opiate and muscarinic cholinergic receptors. The investigators found immunocytochemical staining at the LM and EM level with anti-met^5-enkephalin and anti-leu^5-enkephalin antibodies in undifferentiated cells grown in serum-containing and serum-free defined medium. At the EM level, staining was localized to synaptic vesicles. No staining with β-endorphin or β-LPH antibodies was observed. These cells therefore synthesize enkephalin peptides as well as acetylcholine. In undifferentiated cultures, only 25-30 percent of the cells stained for enkephalins, and staining was localized to rounded or neurite-like cells either singly or in small clusters. When the cells in either medium were induced to differentiate with 1.0 mM dibutyryl cyclic AMP (dBcAMP) in the medium for up to 5 days, there was a progressive increase in the percent of the volume fraction of cells staining, up to 60-70 percent (Figure 1). Staining in differentiated cells was intense throughout the elongated processes which developed and, at the EM level, cells had an increased number of vesicles staining for enkephalins. Thus differentiation of these (and other) neural cells in culture caused greatly increased synthesis of opioid peptides (Braas et al. 1981).

Alpha$_2$-receptors on undifferentiated NG108-15 cells in either medium were labeled with the full agonist ^{3}H-epinephrine (EPI), the partial agonist ^{3}H-PAC, and the antagonists ^{3}H-yohimbine (YOH) and ^{3}H-rauwolscine (RAUW). The NG108-15 α_2-receptor was shown to occur in two states with ^{3}H-EPI and ^{3}H-PAC selectively labeling H, and ^{3}H-YOH and ^{3}H-RAUW labeling both H and L. The total density was 30,000-40,000 receptors per cell. Guanine nucleotides and divalent cations modulated the equilibrium between H and L states as observed for other cyclase-linked receptors (Kahn et al. 1982). To examine regulation, cells were exposed to (−)-epinephrine at 37°C for 0.1-16.0 hours, and binding of various ligands, and the response of inhibition of basal adenylate cyclase was measured in thoroughly washed membranes. The time course of binding and response changes is shown in Figure 2. Like β-receptors, regulation of NG108-15 α_2-receptors by 10 μM (−)-epinephrine appeared to be biphasic. At short exposure times (less than 60 min), there was a shift from L to H states of the receptor, as indicated by an increase in the B_{max} of ^{3}H-EPI and ^{3}H-PAC, with no change in total receptor number (B_{max} of ^{3}H-RAUW), while at the same time there was no change in the maximum receptor-mediated response, but there was a 2-fold reduction in the potency of (−)-epinephrine in inhibiting adenylate cyclase. Therefore this first

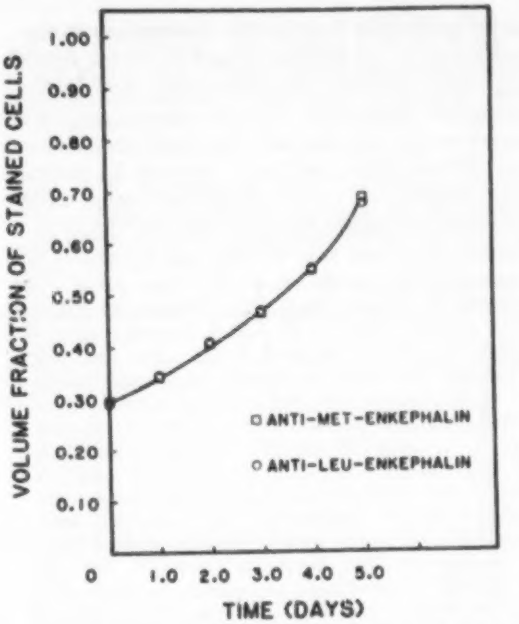

FIGURE 1. Increase in volume fraction of NG 108-15 cells in culture staining for met-enkephalin and leu-enkephalin, as a function of time of incubation of cells with 1.0 mM dBcAMP.

phase of regulation represents uncoupling of the receptor with a concomitant shift to H (desensitized?) states. At longer exposure times there was a progressive reduction in receptor number measured with any ligand, accompanied by no change in maximum response (Figure 2), but a reduced potency of (−)-epinephrine, suggesting the presence of a spare receptor reserve. Other experiments indicated that in this second phase of down-regulation, there was a selective loss of H states of the receptor (Kahn & U'Prichard 1981).

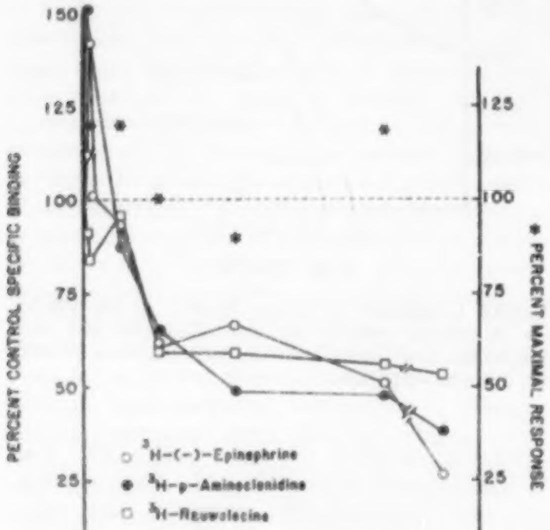

FIGURE 2. Changes in α_2-receptor binding (B_{max}) and adenylate cyclase response (inhibition by epinephrine) in washed membranes as a function of time of exposure of NG108-15 at 37° to 10μM (−)-epinephrine.

In other experiments, rats under mild restraint were continuously infused for 72 hours via the jugular vein with clonidine (0.001-1.0 mg/kg/hr). Infusion of clonidine had a bimodal effect on rat cortex ^{3}H-PAC sites, with lowest concentrations of clonidine increasing ^{3}H-PAC binding 50 percent above control, while higher doses decreased ^{3}H-PAC binding 60 percent below control values. However, rat cortex ^{3}H-RAUW binding (Perry & U'Prichard 1981) was not affected at any clonidine concentration (U'Prichard et al. 1981). This dose-dependent regulation of H states of the α_2-receptor with no change in total receptor population following a fixed time of agonist exposure may parallel the time-dependent bimodal regulation of agonist binding with a fixed concentration of agonist seen in NG108-15 cells.

The above results indicate that there is a phase of α_2-receptor down-regulation where one can observe an *increase* in agonist binding. It is clear that the relationship between changes in monoamine receptor binding and function due to increased agonist exposure, e.g., as a result of antidepressant treatment, can be quite complex, and apparently contradictory data can be obtained which are resolvable once the true significance of binding changes is understood. Regulation of neuronal serotonin receptors and responses can be analyzed in a parallel manner through the use of serotonin receptor-containing neuroblastoma hybrid NG108-15 and NCB-20 cells in culture.

Model Utility in Postpartum Psychosis

James A. Hamilton, Ph.D., M.D.[1]

Over the past half-century many physicians have suspected that severe psychiatric illness which follows childbearing, or postpartum psychosis, is critically related to hormonal changes in the puerperium (Karnosh & Hope 1937; Bürgi 1953). The author noted that very little progress has been made toward translating the suspicions of hormonal involvement into therapeutic applications. Postpartum patients continue to be treated as if they have run-of-the-mill psychiatric diseases, often with unsatisfactory results.

Among the reasons cited for current failure to explore and exploit a likely hormonal component is the fact that the presenting psychiatric syndromes of postpartum patients vary widely and may change abruptly or slowly to other syndromes. Mixed syndromes are of frequent occurrence. Along with the instability of clinical syndromes is a complex and rapidly-changing hormonal situation. The complexity and changeability of the psychiatric and hormonal situations have worked against definitive analysis. Furthermore, the severity of illness, with grave suicidal hazards, has discouraged the pursuit of studies with traditional experimental controls.

The author suggested that the understanding and treatment of patients might profit by the use of models, an approach which has been useful in other complex scientific problems. Specifically, he suggested that known hormonal events be plotted in temporal sequence on a logarithmic scale. Psychiatric phenomena would be superimposed on this scale. In the interest of simplicity, the first model would be limited to a distribution of the first occurrence of symptoms in patients with two constellations of symptoms, those exhibiting agitation ranging to mania, and those whose illness begins with depression. When mixed cases are eliminated, there is reasonable agreement that the first symptoms of the agitated group usually develop from the 4th to the 12th day postpartum, while the first symptoms of the depressed patients usually begin from the 3rd to the 5th week (Karnosh & Hope 1937; Paffenbarger et al. 1961; Pauliekhoff 1964).

Figure 1 indicates thyroid changes in the puerperium. The only comprehensive data on this were reported in 1943 (Danowski). The standard of measurement was protein-bound iodine (PBI), so there is no separation of thyroid fractions. With a pre-pregnancy mean of 5.40, the final mean, 280 days after childbearing, is 4.40. The standard deviation of the final measure is 0.90, so many values are far below the pre-pregnancy range. The author recalculated Danowski's data to eliminate nursing mothers and cases of amenorrhoea and found a value of 4.46 at 280 days. With estrogen cycles back to normal it is difficult to ascribe this low level to anything else than a

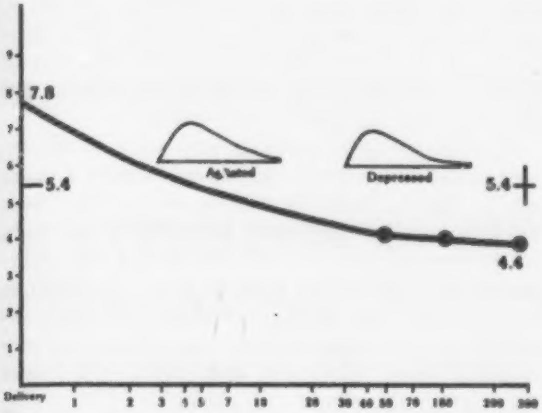

FIGURE 1. Late depression and mean PBI levels.

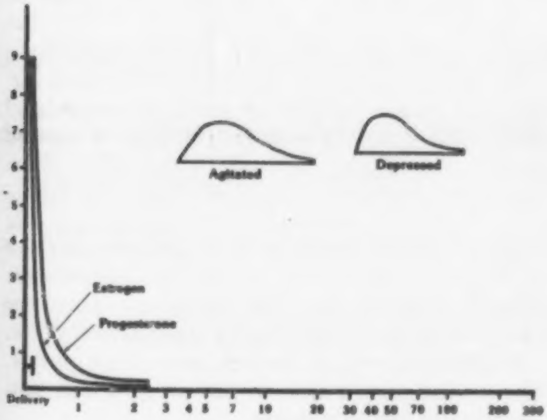

FIGURE 2. Estrogen and progesterone.

substantial, long-lasting drop in the output of thyroxine.

The author noted that postpartum symptoms which begin with depressive symptoms tend to occur as the PBI drop reaches the beginning of its low plateau. Two clinicians with large numbers of cases have reported independently that many cases of depression in the late puerperium respond favorably to thyroid administration, but this form of treatment is not widely accepted (Hamilton 1962; Baker 1967).

Figure 2 indicates the postpartum drop in fetoplacental hormones. The author noted that estrogen and progesterone are at very low levels within 24 hours after delivery, while symptoms of psychiatric illness almost never appear before the 3rd or 4th day. He pointed out that this fact makes it unlikely that deprivation of fetoplacental

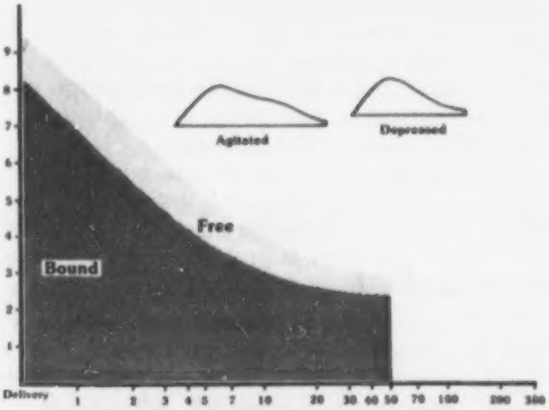

FIGURE 3. Adrenal corticoids: The trend.

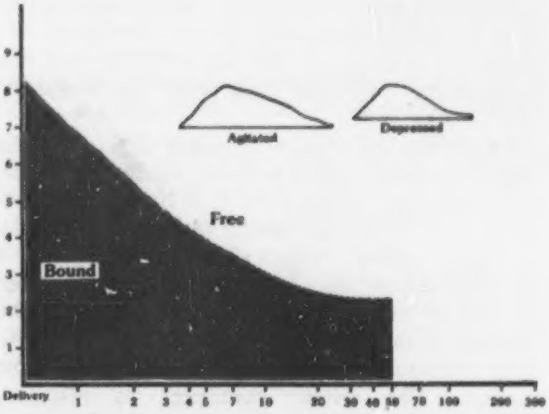

FIGURE 4. Variability of free cortisol: A possible cause of early symptoms.

hormones acts *directly* to produce psychiatric symptoms. Indirect causal effects are not ruled out, and indeed there is some indication that if the postpartum fall in estrogen is cushioned by parenteral estrogen at delivery and for a few days thereafter, high-risk patients may be protected from recurrence of postpartum illness (Hamilton 1977).

Figure 3 is a crude portrayal of the postpartum changes in adrenal corticoids (Tulchinsky 1980). During the latter part of pregnancy, total serum corticoids rise to a level which is three times that of the nonpregnant state. Most of the corticoids are bound to a specific protein, transcortin. About 90 percent of the principal corticoid, cortisol, is bound while 10 percent is free. As corticoids fall over a period of 2 to 3 weeks postpartum, the tendency is for free, physiologically active cortisol to decrease at about the same rate.

However, the author pointed out evidence from the work of Sachar and others indicates that the input of new free cortisol is pulsatile, so that the decrease in corticoids is probably more correctly represented in Figure 4 (Sachar 1973).

The maintenance of optimal levels of free cortisol is mainly achieved through a feedback sensing mechanism located in the hypothalamus. This mechanism generates a peptide releasing factor which is carried by the primary capillary plexus to the anterior pituitary, which in turn releases adrenocorticotropic hormone (ACTH) and thereby stimulates the production of cortisol (Jubiz 1979).

After childbirth the pituitary moves rapidly from hyperemia to ischemia, and its cells change from a phase of hyperactivity to a resting phase. This is reflected in the observation that the postpartum pituitary response is "sluggish" (Tulchinsky 1980).

Inspection of Figure 4 leads directly to a hypothesis with regard to early, agitated postpartum symptoms. During the first 10 days postpartum, total corticoids remain fairly high, but the principal active component, free cortisol, is variable. It may reach a low point, inciting a reaction by its sensor in the hypothalamus, but the response of the "sluggish" pituitary may be insufficient to stimulate the required amount of new free cortisol. The sensor continues to respond, perhaps more and more vigorously. Increased hypothalamic activity may spread to other hypothalamic functions, with sleep disturbance and heightened sympathetic activity, which is perceived as severe anxiety. This kind of disturbance, in the absence of a reasonable cause, could lead to the thinking disturbances which are observed in early postpartum cases.

The foregoing hypothesis is supported by experimental evidence which was reported 8 years ago by Steiner and his associates (1973). These workers treated alternate admissions of early postpartum psychosis with propranolol and chlorpromazine. Only five patients were included in each group, but admission data indicated excellent group comparability. The results with propranolol were strikingly and uniformly better than the results with chlorpromazine. This study, which may well be a landmark in the treatment of postpartum psychosis, has been virtually disregarded. The use of propranolol, a drug with many receptor sites in the hypothalamus, may be a specific medication for responses which can evolve rapidly into early postpartum psychosis.

To explore the model-generated hypothesis further, the author used small doses of propranolol with small doses of sedation to treat a case of known (iatrogenic) corticoid withdrawal which had been unresponsive to other treatment. Symptoms of episodic palpitation, severe anxiety and visceral distress, dyspnea, sleep disturbances and panic which had persisted for 3 months were relieved immediately. The symptoms were very similar to those found in early postpartum cases. The difference was in the response to symptoms. The patient was aware of the event which had precipitated her symptoms.

The case of known corticoid withdrawal is not submitted as a necessary equivalent to early postpartum cases. It is, rather, an instance in which a model-generated hypothesis can stimulate cautious clinical experimentation along lines relating to the area of the hypothesis.

In summary, models can be useful in the visualization of complex psychophysiological relationships, such as may exist in postpartum psychosis. Models, such as that presented, could be useful in relating experimental findings and clinical observations which, without a model, are likely to remain isolated, disconnected, unexplored and neglected. An outstanding and unacceptable fragmentation of this kind is found in the area of psychiatric illness which follows childbearing.

Hormonal Modulation of Central Dopamine Receptor Sensitivity in the Postpartum Period

Umberto Scapagnini, M.D.,[1] Filippo Drago, M.D.,[1] Ferdinando Nicoletti, M.S.,[1] Francesco Patti, M.S.,[1] Mario Matera, M.D.,[1] and Pier L. Canonico, M.D.[1]

It has long been known that neurological or psychiatric disturbances may occur in women in the course of physiological disendocrine states. Depression and/or anxiety, for instance, are frequent in the premenstrual syndrome (Reid & Yen 1981), while there is evidence that postmenopausal women have the highest incidence of tardive dyskinesia (Crane 1968). The postpartum period is associated with sharp hormonal modification, including changes in prolactin (PRL), 17-β-estradiol, or progesterone levels (Rolland et al. 1976).

In the present study, the authors focused attention on the central effects of PRL, estrogens (E), and progesterone (PG) in an attempt to establish whether changes in hormonal levels may be involved in the occurrence of neuropsychiatric disorders, including psychosis, in the postpartum period (Hatotani et al. 1980). As a first step, the authors investigated the effects of PRL, E, or PG on dopaminergic transmission which is apparently implicated in the pathophysiology of psychiatric or extrapyramidal syndromes. Toward this end, the effects of PRL on dopamine (DA)-dependent behaviors such as grooming or motor behavior were investigated in male rats. Animals displayed excessive grooming in conditions of chronic endogenous hyperprolactinemia induced by anterior pituitary transplantation under the kidney capsule (Table 1). This increase in grooming behavior is considered as a consequence of PRL-induced stimulation of nigro-striatal DAergic transmission since it is elicited by i.c.v. or intranigral PRL injection (Table 1). The grooming is apparently prevented by intrastriatal injection of haloperidol or 6-hydroxy-DA injection (Table 1).

Table 1

Influence of PRL on Grooming Behavior

Treatment	Grooming Score
Pituitary homograft	89.0 ± 5.0*
Smooth muscle graft	15.0 ± 2.0*
i.c.v. PRL + intrastriatal saline	72.8 ± 6.1**
i.c.v. PRL + intrastriatal haloperidol	24.2 ± 2.0**
i.c.v. PRL + intrastriatal 6-OHDA	44.9 ± 4.2†
i.c.v. saline + intrastriatal saline	26.2 ± 4.1
intranigral saline	21.2 ± 2.2
intranigral PRL	84.7 ± 5.0‡

Values are mean ± S.E.
*$p = 0.01$ (Student's *t*-test) in comparison with smooth muscle graft,
**$p = 0.01$ and
†$p = 0.05$ (Dunnett's test) in comparison with i.c.v. + intrastriatal saline-injected animals;
‡$p = 0.01$ (Student's *t*-test) in comparison with intranigral saline-injected animals.

As evidence for the hypothesis of a PRL interference with central DAergic function, graft-induced hyperprolactinemia significantly potentiates apomorphine or amphetamine-induced stereotypies (Table 2) and PRL increases striatal DA turnover *in vitro* (Perkins & Westfall 1978). However, the lack of *in vivo* biochemical evidence led the authors to investigate whether PRL may interfere with DA-dependent messages by influencing other neural system functionally linked to DAergic transmission. In this connection, it is remarkable that i.c.v. PRL injection results in a decrease in striatal acetylholine turnover (Wood et al. 1980). In view of the well-documented functional linkage between nigro-striatal DAergic and striato nigral GABAergic transmission (Bartholini et al. 1977), the authors have investigated the effects of hyperprolactinemia on the activity of the GABA-synthesizing enzyme glutamate decarboxylase (GAD, EC 4.1.1.15) in substantia nigra (SN). This parameter mainly reflects the synthesis of GABA at the levels of nigral nerve endings originating from corpus striatum (Fonnum et al. 1974). A significant increase of plasma PRL levels (Table 3) is observed under conditions of hyperprolactinemia resulting from anterior pituitary homograft or acute or chronic injection of sulpiride, a hyperprolactinemic neuroleptic that, at the dose used (2 mg/kg, i.p.), poorly crosses the blood-brain barrier (Benakis & Rey 1976). Involvement of PRL in the effects of sulpiride is also suggested by the evidence that no change in nigral GAD activity is observed in sulpiride-injected hypophysectomized animals (Table 3). Thus, it is tempting to speculate that PRL interferes with the extrapyramidal motor system by influencing, at least in part, strio-nigral GABAergic transmission.

Several studies were performed concerning the influence of E on nigro-striatal DAergic transmission. Specifically, in view of clinical and animal studies, E appear to decrease DAergic tonus. In this line, E have been shown to display a striking effect on L-DOPA or neuroleptic-induced dyskinesia (Bèdard et al. 1979). Moreover, E appeared to potentiate spiperone-induced catalepsy (Chiodo et al. 1979), decrease apomorphine-induced stereotypies (Euvrard et al. 1980), impair DA response on striatal cholinergic interneurons (Euvrard et al. 1979) and increase the number of DA receptors (Hruska et al. 1980). Since hypophysectomy completely prevents these effects (Euvrard et al, 1979; Hruska et al. 1980) it has been proposed that the anti-DAergic activity of estrogens might be mediated by PRL, the secretion of which is strongly stimulated by E (Labrie et al. 1978). However, as above reported, PRL presumably potentiates the DA-related behavioral parameters. We have also demonstrated (Table 3) that E treatment results in a decrease of nigral GAD activity in spite of the high PRL levels. Thus, it is conceivable that PRL does not mediate E central effects but rather displays an opposite effect in comparison with E, at least with respect to the striato-nigral GABAergic system.

In regard to PG, no data concerning a possible interference with the extrapyramidal motor system are available. However, in view of the evidence that pregnancy or oral contraceptive therapy are sometimes associated with chorea (Fernando 1966), it has been suggested that PG can increase DAergic transmission (Bèdard et al. 1979). In the present study we have investigated the effects of PG in patients affected by Parkinson's disease. A preliminary clinical evaluation carried out using semiquantitative scales and electromyography would indicate that PG, in association with L-DOPA + decarboxylase inhibitor (DI) improves the therapeutic efficacy of L-DOPA + DI significantly more than a placebo. This evidence would be consistent with the DAergic hypothesis of PG central effects, even though the mechanism of action of the sexual hormone remains unclear.

Membrane Abnormalities in Schizophrenia[1]

Robert Hitzemann, Ph.D.,[2] and
David Garver, M.D.[2]

Introduction

Recent studies from this laboratory have described a lithium-responsive schizophrenia (Hirschowitz et al. 1980). This disorder is characterized by an acute and remitting illness and thus such patients meet the criteria both for "good prognosis schizophrenia" (McCabe et al. 1971) and Diagnostic and Statistical Manual-III (DSM-III) schizophreniform disorder. In addition, these patients, in contrast to non-lithium responders, show an excessive growth hormone response to apomorphine (Hirschowitz et al. 1982) and an elevated erythrocyte lithium ratio (Garver et al. 1982). The increase in lithium ratio appears to be related to a decrease in Na^+-Li^+ counterflow activity and in some patients to an increase in passive Li^+ leak.

It was hypothesized that the abnormalities in Li^+ transport may be a reflection of a more general abnormality in membrane composition. Indeed, preliminary studies (Hitzemann & Garver 1981) revealed that there was a significant decrease in phosphatidylcholine (PC) levels in the erythrocyte ghost membranes of high lithium ration – good prognosis patients. The magnitude of the decrease in PC is similar to that reported by Stevens (1972) for a general schizophrenic population and subsequently confirmed by Henn (1981).

These authors found an increase in phosphatidylserine (PS) to compensate for the decrease in PC. These data differ from the results in schizophreniform patients where ethalolamine plasmalogen (EP) or sphingomyelin (SP) levels were found to increase in the PC deficient membranes (Hitzemann & Garver 1982). Thus, there is some evidence that there may be differences between schizophrenic and schizophreniform patients as to the membrane lipid abnormalities. In order to examine this issue in greater detail, the authors studied the erythrocyte ghost lipid com-

position of 23 DSM-III schizophrenics, 9 DSM-III schizophreniform patients, and 15 age- and sex-matched controls. The possibility was also examined that the membrane abnormalities in the lithium-responsive schizophreniform patients may impart some unique mechanisms of action to lithium. The first site examined was the phospholipid methylation system (Hirata & Axelrod 1980), since it seemed conceivable that lithium could stimulate methylation and reverse the decrement in membrane PC at critical sites for the regulation of membrane activity.

Method

The patient population used in this study has been described previously (Hirschowitz et al. 1980). All patients undergo a 2-week drug washout prior to sampling. Four of the schizophreniform patients had no prior history of drug use. Three of the control patients had common migraine and were under treatment, aspirin and/or propranalol, for this disorder. Ghost membranes were prepared from well-washed red cells as described by Dodge et al. (1965). The membranes were then analyzed for the content of the major phospholipid classes as described by Horrocks (1968). Phospholipid methylation was measured in *fresh* ghost membranes at pH = 8.0 essentially as described by Crews et al. (1980).

The methylated products were isolated by thin-layer chromotography (Crews et al. 1980). The amount of radioactivity found in phosphatidylethanolamine (PE) was taken to be the blank value and was subtracted from the counts in phosphatidylmonomethylethanolamine (PME), phosphatidyldimethylethanolamine (PDC), and PC. Statistical significance was determined by the Student's *t*-test for unpaired data.

Results and Discussion

The data in Table 1 show that there was a significant decrease from control levels in erythrocyte ghost PC for both the schizophrenic and schizophreniform groups. For most patients, this deficiency in PC was compensated by an increase in SP. Thus, the total amount of lipid-choline (PC + SP) was conserved. These data differ from previous results for schizophreniform patients (Hitzemann & Garver 1982) in which the decrement in PC was primarily compensated by an increase in EP. In this study, the increase in EP was observed in 2 of the 23 schizophrenic and 4 of the 9 schizophreniform patients, suggesting the greater incidence of the EP change in schizophreniform patients but not as great an incidence as reported in the original cohort.

The distribution of the PC data was such that 31 percent PC could be used to discriminate between the control and patient populations. Nineteen of the 23 schizophrenic patients, 9 of the 9 schizophreniform patients, but only 2 of the 15 control patients had PC values less than 31 percent. One of the two control subjects who showed the abnormality was a migraineur. The other control with a low PC level was a medical student with no apparent illness. Overall, these results

Table 1

Distribution of Erythrocyte Ghost Phospholipids in Controls, Schizophrenics, and Schizophreniform-Disorder Patients

Phospholipid	Control $N = 15$	Percent of Total Schizophrenia $N = 23$	Schizophreniform $N = 9$
Phosphatidylcholine	33.7 ± 1.2	29.3 ± 1.1*	28.7 ± 0.5*
Phosphatidylethanolamine	18.8 ± 1.5	17.1 ± 0.9	18.4 ± 1.2
Phosphatidylserine	15.4 ± 1.2	15.1 ± 1.0	15.9 ± 0.7
Phosphatidylinositol	3.1 ± 0.5	2.3 ± 0.2	2.3 ± 0.2
Ethanolamine Plasmalogen	10.3 ± 0.9	12.0 ± [illegible]	11.9 ± 1.1
Sphingomyelin	19.7 ± 0.9	24.1 ± 1.5*	23.3 ± 1.8†

* - Significantly different from control, $p < 0.05$ (two-tailed)
† - Significantly different from control, $p < 0.05$ (one-tailed)

confirm the marked enrichment of the PC deficiency in schizophrenic populations found by others (Stevens 1972; Henn 1981). However, these results do not confirm the increase in PS to compensate for the loss of PC. The reason for this difference is not clear. The data suggest the need for interlaboratory verification of results and standardization of analytical techniques. The observation that a small percentage of controls (13%) gave a "false-positive" result indicates the need to evaluate an extensive and varied control population before it will be possible to use the membrane lipid abnormalities as a "blood-test" for schizophrenia.

Although the membrane abnormalities did not discriminate between schizophrenic and schizophreniform populations, the effect of lithium on erythrocyte ghost phospholipid methylation did discriminate between these groups. The kinetics of phospholipid methylation in erythrocyte ghosts in shown in Table 2. These data confirm the results of others (Hirata & Axelrod 1980) that methylation is probably catalyzed by two methyltransferases, inasmuch as the Km for [^{3}H] PME formation (0.92 uM) is distinctly different from that for [^{3}H] PDE (2.74 uM) and [^{3}H] PC (3.15 uM) formation. A concentration of 3 uM [^{3}H] S-adensoylmethionine (SAM) or approximately the apparent Km concentration for methyl-transferase-II was used in subsequent studies.

The data in Table 3 show the effect of lithium (0.5 and 1.0 mM) on phospholipid methylation in erythrocytes ghosts prepared from controls, schizophreniform-disorder patients, and schizophrenics. The lithium effects were highly individual. For example, in controls #1 and #3, lithium had relatively little effect on methylation while on control #2, lithium inhibited methylation, particularly the formation of [^{3}H] PME. In contrast, lithium markedly stimulated [^{3}H] PME formation in the schizophreniform patients, although the magnitude of the increase was quite variable, e.g., from 158 percent in Patient #2, to 646 percent in Patient #1. Lithium either inhibited or had no significant effect on phospholipid methylation in three schizophrenic patients. Although the sample is quite small, these data suggest that further study of the phospholipid methylation system as a potential site of lithium action is warranted.

Table 2

Kinetics of Phospholipid Methylation In Human Erythrocyte Ghost Membranes*

Parameter**	[^{3}H]PME	[^{3}H]PDE	[^{3}H]PC
Km†	0.92	2.74	3.15
Vmax†	2.81	6.38	14.67

*Various concentrations of [^{3}H]SAM (.1 to 10 μM) were used to determine the kinetic plots. The methylated products were isolated by thin layer chromotography (Crews et al. 1980).

**The kinetic parameters, Km and Vmax, were determined as described by Wilkinson (1961).

†Km - μM; Vmax - p mol/mg protein/30 min.

Table 3

Effect of Lithium on Phospholipid Methylation in Controls, Schizophrenics and Schizophreniform-Disorder Patients*

Group	[Lithium] mM	Percent of Control (no added lithium) [^{3}H]PME	[^{3}H]PDE	[^{3}H]PC
Control #1	0.5	96	97	90
	1.0	93	97	93
Control #2	0.5	49	90	90
	1.0	32	74	60
Control #3	0.5	82	84	76
	1.0	103	103	101
Schizophreniform #1	0.5	300	23	105
	1.0	646	84	155
Schizophreniform #2	0.5	125	149	202
	1.0	158	214	214
Schizophreniform #3	0.5	225	98	139
	1.0	323	152	219
Schizophrenic #1	1.0	60	91	85
Schizophrenic #2	1.0	82	104	68
Schizophrenic #3	1.0	67	75	76

*Methylation was measured as described in the legend to Table 2 except that 3 μM [^{3}H]SAM was used in all experiments and various concentrations of lithium were added in vitro. All incubations were done at 37 °C, pH = 8.0 and in the presence of 2 mM $MgCl_2$. Data are expressed as percent of the value obtained in the absence of lithium.

Phospholipids and Phospholipid Methylation in Platelets and Brain

Donna Mandio Cordasco,[1] David Wazer,[1] David J. Segarnick,[1] Andrew Lautin, M.D.,[1] Arnold Lippa, Ph.D.,[2] and John Rotrosen, M.D.[1]

Recent studies of membrane phospholipid composition and metabolism indicate that phospholipids are integrally involved in regulating membrane biochemistry and biological signal transmission. In all biological organisms, bilayer membranes separate the intracellular cytosol from the extracellular environment and provide a supportive matrix within which numerous "membrane-bound" enzymes and proteins reside. Phospholipids are the major structural components of membranes, and synthetic phospholipids will spontaneously form membrane-like bilayers in aqueous media. In biological membranes (unlike artificial bilayers) the phospholipids are nonrandomly distributed between the two membrane leaflets. For example, in erythrocytes, phosphatidylcholine (PC) is primarily localized on the extracellular membrane surface, while phosphatidylserine (PS) is nearly all localized on the inner cytoplasmic membrane surface [these asymmetries are tissue-specific, e.g., in platelets PC is evenly distributed between the two membrane surfaces (Zwaal et al. 1977)]. Recent research indicates that phospholipid asymmetry effects cellular function by altering surface charge and membrane fluidity.

Certain aspects of membrane asymmetry are reflected in the enzymatic biosynthesis of (PC) through successive N-methylations of phosphatidylethanolamine (PE). Two enzymes catalyze this reaction sequence. The first enzyme which is located on the inner, cytoplasmic surface of the membrane synthesizes phosphatidyl-N-monomethylethanolamine (PME) by adding one methyl group to PE. The second enzyme is located near the outer membrane surface and

[2] Lederle Laboratories, Division of American Cyanamid Co., Pearl River, NY 10965.

adds two additional methyl groups to PME to form phosphatidyl-N,N-dimethylethanolamine (PDE) and PC. S-adenosyl-L-methionine (SAM) is the methyl donor for both enzymes. In erythrocytes, the products of phospholipid methylation are asymmetrically distributed; PME is localized on the intracellular membrane surface while PDE and PC are on the extracellular surface (Hirata & Axelrod 1978). This product distribution is established through a flip-flop mechanism whereby PME is translocated through the lipid matrix and methylated to PDE and PC on the extracellular side of the bilayer. Associated with phospholipid methylation are localized changes in membrane fluidity, and receptor exposure (Strittmatter et al. 1979a), Ca^{++} ATPase activity (Strittmatter et al. 1979b), receptor-cyclase coupling (Hirata et al. 1979) and other membrane-mediated events.

Phosphatidylserine, a negatively charged phospholipid, is almost exclusively localized on the inner membrane leaflet in red blood cells (Zwaal et al. 1977); recent reports (Henn 1981) suggest that PS may play an important role in the etiopathology of schizophrenia. PS is unique amongst the phospholipids insofar as it has a number of "pharmacologic" effects when administered (in low doses) *in vivo* or (at low concentrations) *in vitro*. Amongst these are the following central nervous system (CNS) effects: PS causes a rapid increase in acetylcholine release in rat cortex (Mantovani et al. 1976), it increases levels of homovanillic acid in rat brain, and enhances norepinephrine turnover in rat hypothalamus (Toffano et al. 1978). A study by Stevens (1972) which has recently been replicated by Henn (1981), indicates that schizophrenics' red blood cells contain approximately 40 percent more PS and 10-15 percent less PE and PC than red blood cells from controls.

Preliminary work from our laboratory investigating phospholipid methylation and membrane phospholipid composition is described.

Platelet Phospholipid Methylation

Since platelets have many properties in common with monoaminergic neurons and are often used in psychiatric research as peripheral models of CNS biochemistry, the authors undertook to study the role of phospholipid methylation in the regulation of platelet function.

Phospholipid methylation was assayed by incubation of intact platelets with ^3H-methionine as previously described (Cordasco et al. 1981). Three major lipid extractable products—PME PDE, and PC were synthesized. Formation of these products was pH, time- and temperature-dependent, and saturable with respect to precursor concentration. As in other tissue types, platelet phospholipid methylation is sensitive to certain agents which elicit tissue-specific responses. Physiological concentrations of epinephrine, adenine, and thrombin inhibited formation of ^3H-methylated phospholipids. In some aspects, however, phospholipid methylation in platelets differs from that in other tissues.

Although phospholipid methylation is a minor pathway for PC biosynthesis, in leukocytes methylation derived PC comprises a discrete, highly active pool which is the primary source of free arachidonic acid released in response to chemoattractants (Hirata et al. 1979). In the interest of determining whether platelets also contain differentially active PC pools, platelet PC was labeled by incubation with ^3H-methionine, ^3H-choline, or ^{14}C-arachidonic acid and then stimulated arachidonic acid release with thrombin. PC synthesized from each of the three precursors was equally reduced by thrombin treatment indicating that in platelets, PC formed through methylation does not comprise a functionally distinct pool.

Table 1

Product Remaining After Phospholipase C Digestion (% of Control)

	3H-PME	3H-PDE	3H-PC
No Phospholipase C	100	100	100
Phospholipase C Incubated with Intact Platelets	80	74	66
Phospholipase C Incubated with Lysed Platelets	17	16	14

Phospholipase C digestion of 3H-PME, 3H-PDE, and 3H-PC in intact or osmotically lysed pre-labeled platelets. Values are expressed as % of control samples which were run with each assay and did not contain added phospholipase C.

A further distinction between phospholipid methylation in platelets and in other tissues lies in the distribution of tritiated PME, PDE, and PC between the cytoplasmic and extracellular membrane surfaces. Intact and hypotonically lysed platelets were enzymatically digested with phospholipase C to determine the localization of ^{3}H-methylated phospholipids (Table 1). The products of platelet phospholipid methylation were found to be equally distributed on the intracellular and extracellular membrane surfaces. The symmetrical distribution of methylation derived PC in platelets is compatible with a report by Zwaal et al. (1977), indicating that total platelet membrane PC is also symmetrically distributed (in contrast to asymmetrically distributed erythrocyte membrane PC).

Given the differences in the pharmacological and biochemical characteristics of phospholipid methylation in platelets and other tissues (including synaptosomes), the authors question whether studying platelet phospholipid methylation in psychiatric patients will be of value as a model of CNS function.

Synaptosomal Phospholipid Methylation

In erythrocytes (Hirata et al. 1979) and cultured astrocytoma cells (Strittmatter et al. 1979c), agonist stimulation of β-receptors increases phospholipid methylation. These findings and their potential implications in neuroscience have encouraged the authors to examine norepinephrine (NE) stimulation of synaptosomal phospholipid methylation.

The ability of NE to enhance phospholipid methylation was assessed in a crude synaptosomal preparation by the method of Crews et al. (1980). NE stimulation consistently increased chloroform extractable radioactivity by 100% - 200% initially suggesting that NE stimulated phospholipid methylation. In order to verify product identities, the authors chromatographed the extracts in three thin layer chromatography (TLC) systems and serially scraped the TLC plates. The serial scrapes revealed several large NE-stimulated peaks of radioactivity which could not clearly be attributed to 3H-PME, 3H-PDE, or 3H-PC but which chromatographed with these methylated phospholipids in some TLC systems.

Table 2

	Chromatography System		
Product	(1)	(2)	(3)
PME	+	+	–
PDE	–	+	–
PC	–	+	+

NE stimulation of phospholipid methylation as observed in three chromatography systems. + indicates NE stimulated increase in radioactivity co-chromatographing with authentic standards of PME, PDE, or PC.

(2) = chloroform:methanol:4N ammonium hydroxide 70:35:4
(3) = chloroform:acetone:methanol:acetic acid:water 10:4:2:2:1

When the results from the three chromatography systems are compared (Table 2), it is apparent that the NE induced stimulation does not consistently correspond to PME, PDE, or PC indicating that NE does not stimulate phospholipid methylation under the conditions studied. In an attempt to identify the NE-stimulated product or products, several methylated substances which were reasonable candidates were chromatographed in the three previously described chromatography systems (Table 3). A test-substance must co-chromatograph with a NE stimulated peak in each of the three systems for a positive correlation to be made. To date, no substance has met these criteria and the chloroform extractable, NE stimulated products have not been identified.

Phospholipid Methylation in Aging

Comparative studies of phospholipid methylation were undertaken in synaptosomes from young adult and aged rats. The process of phospholipid methylation alters membrane fluidity and also generates PC which can be metabolized to free choline (Blusztajn & Wurtman 1981). Since both membrane fluidity and cholinergic neurotransmission are altered during the aging process, the authors theorized that phospholipid methylations may either underlie these processes, or be modified in a compensatory way in older animals.

Phospholipid methylation was assayed in cerebral cortical synaptosomes from 5- and 24-month-old rats. Accumulation of 3H-PME was significantly increased in the tissue preparation from the older rats, while 3H-PC was unaltered (Table 4). This data is in agreement with results of a similar study (Crews et al. 1981).

Erythrocyte Phospholipids in Schizophrenia

In clinical studies (similar to those presented in this session by Fritz Henn), we have investigated alterations in erythrocyte membrane lipid composition as a marker for schizophrenia. Henn has reported that schizophrenics' erythrocytes differ markedly from those of controls in the distribution of the major membrane phospholipids. Phosphatidylserine levels are elevated (40% > controls) while PE and PC levels are decreased (15% < controls). The authors' laboratory has initiated a pilot study attempting to replicate these findings. Preliminary data (Table 5) indicate that red blood cell membranes from schizophrenics do not differ significantly from those of controls in lipid composition. Discussions with Henn suggested that differences in methodology may account for the discrepancies between the authors' data and his. The authors have conducted a series of experiments employing Henn's extraction methods, but are still unable to identify any substantive differences between schizophrenics and controls.

Table 3

Cellular Actions and Localization of Beta-Carbolines and Tetrahydroisoquinolines

Floyd E. Bloom, M.D.[1] and Jack D. Barchas, M.D.[2]

One of the more intriguing scientific issues in neuropharmacology is the hypothesis that novel metabolites of the monoamine transmitters norepinephrine, dopamine, or serotonin may be formed in the body during ethanol intoxication. In the test tube, it is abundantly clear that the metabolic product of ethanol, acetaldehyde, can condense with the catecholamine transmitters to form a class of chemical called tetrahydroisoquinolines (TIQs), and with serotonin to form the class of compounds termed tetrahydro-beta-carbolines. When these compounds are administered to animals, they have been shown to be very active in altering behavior, transmitter actions, and neuronal activity. In fact, some scientists have proposed that such compounds could underlie the addictive properties of ethanol. This view is based upon experiments in which rats that have received several injections of certain TIQs into their brains will then greatly increase their voluntary consumption of alcohol for many months afterwards. Unfortunately, this intriguing issue is also one of great controversy, and the arguments rage on two fronts: Are these compounds actually ever formed in the brain of humans or experimental animals in relationship to the alcohol they consume and, secondly, do the effects of these compounds help us understand either the basis for intoxication or the mechanisms by which certain individuals become dependent on alcohol?

In an attempt to come to some closure on the most controversial aspects of the biological significance of these elusive substances and their possible broader medical implications, an international workshop was held at the Salk Institute Alcohol Research Center on December 12 and 13, 1981, supported by a supplemental grant from NIAAA. The Workshop, organized by Drs. F. Bloom (Salk Institute), J. Barchas (Stanford University), E. Usdin (National Institute of Mental Health) and M. Sandler (Queen Charlotte's Maternity Hospital), brought together scientists from throughout the United States and Europe for an extensive discussion of the alleged endogenous compounds, their relationship to tissue ethanol content, and the possible actions that—if formed—could be produced in experimental animals. The proceedings of this meeting will be published later this year; the present report summarizes some of the highlights and critical points of the meeting.

The premiere question which faced the workshop was whether these compounds can actually be measured in the body of experimental animals or human subjects and, if so, whether the amounts measured can in any way be influenced by prior ingestion of alcohol. Molecules in tissue fluids or in extracts of homogenized tissues can be measured in many ways, and the methods vary considerably in their accuracy and sensitivity. Among the most sensitive and specific of the available methods are determinations by mass spectrometry. When these methods are applied to the measurements of beta-carbolines, it has so far proven to be extremely difficult to detect them under conditions in which the chemical being measured can be rigorously documented to have arisen in the animal rather than in the test tube during extraction and preparation of the sample for measurements. Thus, while there are several published reports that beta-carbolines can be extracted from human urine, spinal fluid, or from platelets after ethanol exposure, it is difficult to rely strongly on such reports without convincing evidence that the already detected sources of contaminating aldehydes, and other sources of artifactual carboline formation, have wholly been eliminated. Furthermore, many at the workshop shared the view that even if beta-carbolines could be authenticated as endogenous constituents of urine or platelets, this is insufficient to document their endogenous occurrence in central or peripheral nervous tissue.

[2] The Nancy Pritzker Laboratory for Behavioral Neurochemistry, Stanford University Medical School, Stanford, CA 94305.

The most "negative" series of detection attempts were reported by Dr. T. Bosin, presently of Indiana University, who perfected his methodology in the Laboratory of Dr. Bo Holmstedt of the Karolinska Institute. In the course of these studies, Bosin and Holmstedt recognized that beta-carboline-like structures were arising during the preparation of the samples to be measured, and that to a large extent these artifactual formations far outweighed the beta-carboline that might have been present in the original tissue or biological fluid source. Important sources of these artifactually formed carbolines included covert formaldehyde and acetaldehyde contamination of even extremely pure reagents such as dichloromethane and chloroform, and the nitrogen gas used to dry the specimens. In some cases Bosin inferred that significant aldehyde contamination could even have existed in the distilled water supply. Although the absolute amounts of such contaminating aldehydes may be relatively small, the amounts of presumptive carbolines are already vanishingly small and, in the hands of Bosin, disappear completely when steps are taken to trap out the contaminants. A particularly perplexing contaminant was their discovery that the 5-HT source to be used as an internal standard was itself contaminated with carbolines.

Similar problems of internal chemical contamination contributing to the exogenous formation of beta-carbolines during sample preparation also led Dr. Kym Faull of Stanford University to conclude that he was unable to document the endogenous formation of any beta-carboline in rat brain except for tetrahydro-beta-carboline (THBC), and the maximum amount detectable here was less than 0.5 nanogram/brain. This group terms indoleamine-aldehyde condensation products tryptolines using a serotonin numbering system. Using a form of mass spectrometry (negative chemical ionization with capillary columns) that would have permitted detection at 100 picograms per sample or below, Faull could not find evidence for the carboline products of tryptamine with acetaldehyde, serotonin with formaldehyde or acetaldehyde, or 5-methoxytryptamine with formaldehyde. The Stanford group is very concerned about artifactual formation; however, THBC, if verified, could have important implications, as it would strongly suggest that tryptamine (from which THBC is formed by the addition of formaldehyde) could exist as a transmitter substance independently of 5-hydroxytryptamine, much in the same way that dopamine exists as a transmitter independently of norepinephrine. THBC was shown to be the most potent displacer of $[H^3]$-tryptamine in ligand binding studies reported to the workshop by Dr. K. Kellar (Georgetown University), and those data would support the possibility of a functionally independent tryptaminergic system.

On the other hand, Dr. Steve Barker (University of Alabama), also using GC/MS, detected extremely large amounts of carbolines (500-1000 nanogram/g) in the adrenal glands of singly housed rats, as well as in their brains (20-50 ng/g). Barker conjectured that his values were so high because the rats were under the stress of isolation; the amounts he measured were considerably lower, although well above his threshold for detection, in rats which were group housed. Dr. Olaf Beck, also of the Karolinska Institute, was able to confirm that beta-carbolines could be detected in the urine of rodents and humans, and that it could be elevated after a drinking episode. However, even in this case, Beck found it difficult to conclude that the carboline was formed *in vivo* from aldehyde byproducts of the alcohol metabolism. He favored instead the possibility that the carbolines may have arisen from dietary sources, including the alcoholic beverages themselves, since foods such as cheeses and fruits, especially grapes, are known to have high carboline content.

A somewhat stronger case was developed for the natural occurrence of aldehyde condensation products of the catecholamines. In this case, the resulting TIQs have been more reproducibly documented in tissue and body fluid extracts, and have been shown to be elevated further by recent alcohol ingestion. This body of evidence was comprehensively summarized by Dr. Mike Collins of Loyola University, Chicago, and by Dr. Gerald Cohen, of Mt. Sinai Hospital Medical School, New York. Dr. Birgitta Sjoqvist of the Karolinska Institute pursued the question of whether the particular TIQ which she was able to measure in the urine and cerebrospinal fluid (CSF) of non-alcoholic humans and in higher amounts in urine and CSF of acutely intoxicated humans, originated in the central nervous system; she measured TIQs in postmortem brain specimens from alcoholic and control subjects. Her results indicated that TIQs were detectable in amounts of 20-50 ng/g in dopamine-rich regions such as caudate and putamen, as well as in regions with much less dopamine, such as cerebral cortex and hippocampus. In general, the levels were 5 to 10-fold lower in control (non-alcoholic subjects) and in alcoholics who had died while sober for at least 2 weeks, although underlying neuropathologic consequences of the long-term alcoholism, which reduced endogenous dopamine and increased the content of its metabolite, homovanillic acid, may have contributed to the differences.

On the other hand, attempts by Drs. T. Shier and L. Koda (Salk Institute) to show the formation of DA-related TIQs in the brains of normal or ethanol intoxicated rats by following products formed from intraventricularly injected [H^3]-dopamine, failed to detect any known TIQ, with a method capable of detecting femtomolar amounts. Taken at face value, however, the data from human and some animal studies (summarized by Collins, and by M. Hirst, University of Western Ontario) would certainly be compatible with the view that TIQs may arise normally during catabolism of dopamine or norepinephrine, even without ethanol, and that larger amounts can be formed in the presence of alcohol, perhaps through the classical non-enzymatic condensation reaction of Pictet-Spengler. Dr. Virginia Davis (Veteran's Administration Hospital, Houston, Texas) presented the observations which had led her to hypothesize that tetrahydropapaveroline (THP) might also arise in a similar fashion by condensation of dopamine and dopa-acetaldehyde during dopamine metabolism in the presence of ethanol, but no new data documenting the occurrence of THP in brain or body fluids were presented.

Theoretical calculations by Dr. Henry Weiner (Purdue University) based upon known amounts of catecholamines and known rates of metabolism, and theoretical yields for the condensation reaction conditions which would exist *in vivo*, suggested that conclusive proof that beta-carbolines and TIQs did not exist may be difficult to obtain given that the maximum amounts which could be found could still be below the minute levels towards which the chemists had pushed the levels of detectability. A provocative idea, which appeared at least partially supported by existing data, was the possibility raised by Dr. A. Brossi (National Institutes of Health, Bethesda, Maryland) that TIQs arose not from acetaldehyde dopamine condensations, but rather from pyruvate-dopamine condensations in which oxidative decarboxylation lead to quinoline formation. If this suggestion could be validated, it might answer the unsettled puzzle of how measurable TIQs could be found when acetaldehyde remains below detectable levels.

The Workshop then turned its attention towards possible biological effects which beta-carbolines and TIQs might mediate. The majority of such studies were based on characterizing the pharmacological actions of synthetic carbolines and TIQs, while overlooking—at least for the moment—the critical issue of endogenous formation and its relevance to ethanol intoxication. In fact, several series of interesting biological actions were reported, but it is critical to realize that all such actions required doses of carbolines or TIQs which are orders of magnitude greater than even the most optimistic endogenous measurements.

The workshop participants heard a broad range of observations reported which indicated that synthetic TIQs and carbolines could exert actions at almost every step of monoaminergic function, including interactions with monoamine transmitter ligand binding sites (K. Kellar, Georgetown University, Washington, D.C., and Y. Nimit, VA Hospital, Houston, Texas), possible endogenous inhibitors of monoamine oxidase (M. Sandler, Queen Charlotte's Maternity Hospital, London), and monoamine transmitter synthesis rates (R. Bruce Holman, University of Redding, U.K., and Dr. C. Coscia, St. Louis University) as well as benzodiazepine binding sites (K. Braestrup, A/S Ferrosan, Roskilde, Denmark, and S.M. Paul, NIMH, Bethesda, Maryland), and benzodiazepine actions on sleep stages (W. Mendelson, NIMH, Bethesda, Maryland).

Many of the pharmacological studies of beta-carbolines and TIQs could be viewed as tests of the general hypothesis that addictive or reinforcing properties of ethanol could be mediated by an ethanol-derived condensation product, and the related subhypothesis that such products produced their effects by interaction with one of the endogenous opiate peptide systems.

At the level of single neurons, a strong case for such relationships was established by G. Siggins (Salk Institute) who reported that synthetic salsolinol and 7-methoxy salsolinol (the TIQ formed from dopamine and acetaldehyde) applied by micro-iontophoretic methods, and ethanol, applied by micro-pressure pulse ejection tended to affect neuronal discharge in various brain regions with a qualitative pattern similar to the effects of opiate peptides in these same regions. In general, all compounds were inhibitory in all regions except hippocampus, where all produced excitatory actions. Furthermore, many of the opiate like excitatory responses of hippocampal neurons to ethanol or salsolinal could be antagonized by parenteral or locally applied opiate antagonists. However, the TIQ and ethanol effects were also antagonized by the cholinergic receptor antagonist scopolamine, suggesting that the sites at which TIQs are able to elicit effects are not restricted to endogenous opiate receptors. It is possible that the TIQs, opiates, and ethanol share common actions through an ion channel effect, such as the changes in transmembrane Ca movements described by D. Ross (University of Texas Medical School, San Antonio, Texas).

At the level of the behaving animal, an intriguing set of data which furthered the uncertain linkage between TIQ effects and endogenous opiates was presented by H. Altshuler (TRIMS, Houston, Texas). After laboriously training rats in a two-way drug discrimination task (in which animals reliably gave one response when injected with low intoxicating doses of ethanol and another response when injected with saline), Altshuler investigated the degree to which rats could generalize (or discriminate) their response to potentially related drugs. For example, neither ethanol nor THP (when injected into the cerebroventricles) could produce an effect interpreted by the rats as "like intraperitoneal ethanol"; likewise, acetaldehyde injected either into the cerebroventricles or intravenously was also interpreted as "not alcohol." However, the injection of 50 ng doses of salsolinol intracerebroventricularly was generalized as alcohol-like, and this effect could be antagonized by the opiate antagonist naltrexone. In a conceptually related experiment, Altshuler also reported that he had been able to train some baboons to self-administer oral ethanol and, in a well-balanced control series of animals, he had observed the ethanol self-administration was significantly diminished by naltrexone or another opiate antagonist, naloxone. However, the doses are higher than those required to antagonize injected opiates.

It was, of course, evident to all those at the workshop that a very controversial series of ethanol self-administration experiments had fanned the embers of the various carboline-TIQ hypotheses of ethanol dependence at a time when strong supportive data in the central nervous system had been lagging. Those experiments, reported in the early 1970s by R.D. Myers and his colleagues (*see* Myers 1980; Dietrich & Erwin 1980; Melchior & Collins 1982) indicated that intracerebroventricular injections of THP and certain other TIQs could cause permanent increases in voluntary alcohol ingestion in rats. Although there have been some replications of the basic observation, the original phenomenon has proven to be far from reproducible even when rat species, strain, injection technique and evaluation methods are followed stringently. Furthermore, J.D. Sinclair (Alko, Finland) reported at the workshop that when he and Myers attempted to replicate this experiment together in the Myers' laboratory, they were unable to replicate the THP effect reported previously, although some rats given infusions of beta-carbolines did show modest increases in ethanol ingested.

Dr. Z. Amit (Concordia University, Montreal) reported that he had been unable to replicate the enhancement of ethanol ingestion in rats with any carboline or TIQ, but that he had been able to demonstrate to his own satisfaction that rats would self-administer salsolinol intravenously. However, even rats which exhibited salsolinol self-administration would not accept ethancl as a substitute nor consume significant amounts of oral ethanol. Dr R. Dietrich (University of Colorado Alcohol Research Center, Denver, Colorado) reported that he and his colleagues had in part replicated the THP effect on increased ethanol consumption, but noted that the amounts of ethanol ingested were in general quite modest, generally less than 5 g/kg/day. Others noted that rats which seemed to give the greatest increase in consumption were those with lower initial intake before drug infusion; after the THP treatments the levels consumed by these rats then approached the levels consumed by uninjected controls.

Dr. C. Melchior (University of Illinois Medical Center, Chicago, Illinois) who had participated in the original Myers experiments turned her attention in the interim to the possible interactions between the development of ethanol tolerance and the importance of environmental cues, in order to confront more directly the possibility that such cues could help to distinguish physiological factors which regulate the development and expression of tolerance. In these experiments, mice were trained by receiving daily injections of various doses of ethanol in one laboratory setting with distinctive lighting and sensory cues, and then subsequently tested for the hypothermic effects of a test dose of ethanol either in the training environment or in a novel testing environment. A purely metabolic effect of prior ethanol injection was ruled out in a separate group of mice who were exposed to the same training environments but received their ethanol only in their home cages. Although some tolerance developed in all mice, hypothermia was much less pronounced (i.e., tolerance was greatest) in those mice tested in their training environments. In an extension of these studies, Melchior also observed that injection of 3-carboxyl salsolinol or THP could regulate this process, appparently preventing the development of tolerance by diminishing, through an unknown mechanism, the brain ethanol content in response to the test i.p. dose. She then linked this effect to the earlier reports on THP increasing ethanol consumption by suggesting that one effect of the THP could be to inactivate normal adaptive mechanisms which would normally act to suppress ethanol consumption, perhaps by interfering with the release or effects of some natural transmitter system.

This workshop helped to crystallize certain important open issues which must be experimentally settled before it can be stated that any carboline or TIQ mediates an action of ethanol. The primary open issue is the establishment of the formation of these compounds *in vivo* in nervous tissue in any system in which the formation can be shown to be linked to ethanol content of the tissue, rather than to an artifact of the measuring methods. The evidence available at the time of the workshop seemed to most observers to favor the interpretation that the existence of carbolines under verified uncontaminated conditions was doubtful. The evidence was somewhat more convincing that TIQs formed in brain without ethanol and were increased after long-term ethanol exposure.

The next major open issue was whether the effects ascribed to injections of hundreds of nanograms of these compounds could be considered relevant to the issue of whether if formed endogenously in picogram amounts their release and actions could in any way be shown to be analogous to the effects of the ethanol. Again, the data presented were intriguing and interesting, but far from comprehensive and reproducible. Several actions of TIQs, those on single neurons and those on animals exhibiting one or another effect of ethanol, seemed to be generally similar and antagonized by opiate antagonists. At the same time, a variety of transmitter ligand binding sites were also found to be capable of weak interactions with synthetic carbolines and TIQs.

A third open issue centers on the interpretation of the relatively low doses of ethanol ingestion which some investigators have been able to observe after central injections of TIQs or after other drug treatments. Some held that any treatment that will cause experimental subjects to increase their consumption of ethanol is interesting if the phenomenon to be studied is defined as the basis for ethanol consumption. Others took the view that the critical phenomenon to be studied is the intoxicating and reinforcing pharmacological actions of ethanol which require detectable blood and tissue alcohol levels. Under the latter view, experimental perturbations which increase ethanol consumption above baseline but not far enough above to give detectable blood alcohol levels may be dependent upon totally different mechanisms than those which maintain excessive alcohol consumption in humans.

These three major open issues then can be distilled to one final important question: Given the rather marked disparity between the observed endogenous levels of these substances and their pharmacologically effective concentrations, is it possible to conceive of circumstances in which the necessary pharmacological levels could be attained and measured in a discrete locale, like a synaptic cleft? Although this and other solid issues offer an attractive hypothetical motivation for further research, it seems likely that the will-of-the-wisp nature of these pharmacologically potent substances is likely to persist for some time. Solution to these open questions would, however, be of important benefit to the explanation of problems of alcohol and opiate abuse.

The Effect of a Methadone Challenge on the Prolactin and Growth Hormone Responses of Psychiatric Patients and Normal Controls

Lewis L. Judd, M.D.[1,2] S. Craig Risch, M.D.,[1,2] Donal C. Parker, M.D.,[3] David S. Janowsky, M.D.[1,2] David S. Segal, Ph.D.,[1] and Leighton Y. Huey, M.D.[1,2]

The endogenous opiate-like peptide systems appear to be implicated in a number of important behavioral and physiological functions. The authors, like others, have been interested in the potential role endorphins may play in the pathophysiology of major psychiatric disorders. Based on previous studies, the authors hypothesized that a potentially important interrelationship may exist between the endogenous opioid peptide systems, specific neuroendocrine regulatory factors, and affective disorders (Judd et al. 1981, in press).

Endorphins are involved in the regulation of two neurohormones which have been reported to be abnormal in some depressed patients; these are prolactin (Gold et al. 1978; Judd et al. 1981) and growth hormone (Koenig et al. 1980; Meites et al 1979; Shaar et al. 1977). There have been conflicting reports in the literature on prolactin levels in depression, but Asnis et al. (1980) and Linkowski et al. (1980) have reported lower basal prolactin levels in depressed patients. In addition, Linkowski et al. (1980) and Extein et al. (1980) both reported blunted prolactin responses to respective challenges of thyrotropin-releasing hormone (TRH) and morphine in depressive disorders.

It has also been reported that growth hormone responses to various provocative agents are blunted in depression. Specifically, growth hormone responses to L-DOPA, insulin-induced hypoglycemia, and to amphetamine—all potent stimulators of growth hormone release—are absent or diminished in depressed patients (Sachar et al. 1975; Langer et al. 1976).

Here we report the results of a methadone challenge on prolactin and growth hormone responses in a diagnostically mixed sample of psychiatric patients and normal controls.

Method

Forty-one medically healthy male psychiatric inpatients and normals participated in the study after completing informed consent procedures. The patients' research diagnoses were derived by

the Schedule for Affective Disorders and Schizophrenia-Research Diagnostic Criteria (SADS-RDC) method, and were based upon independent agreement of two psychiatrists. There were four experimental groups as follows: Schizophrenics, $N = 8$, age range 23-45 years, mean age 31.1 years; Manics, $N = 6$, age range 22-46 years, mean age 34.2 years; Depressive Disorders, $N = 16$, age range 22-54 years, mean age 35.86 years; Normal Controls, $N = 11$, age range 22-32 years, mean age 24 years. Subjects were drug-free at time of testing, with the patients having been removed from all psychoactive agents 7 days prior to the experimental sessions. It should be noted that several subjects required single doses of phenothiazines for clinical management a day or two preceding the experiment. Sessions began at 9:00 a.m. with the placement of a heparinized intravenous catheter to which the subjects were allowed 30 minutes for accommodation. Following this, blood samples were drawn once at baseline and at 30 and 60 minutes following the administration of 10 mg intramuscular (i.m.) of methadone-HCl. All the samples were assayed in duplicate within the same assay and blindly by those performing the assay (Parker et al. 1973).

Results

The results of the prolactin assay are included in Table 1. As anticipated, methadone increased prolactin secretion for the entire subject sample from a mean baseline level of 11.7 ± 1.5 ng/ml to a peak of 27.5 ± 5.25 ng/ml at 60 minutes post methadone ($t = 2.78$, df = 40; $p < 0.01$). Methadone induced a mean prolactin rise of approximately two- to three-fold over baseline levels in all four groups of subjects. There were, however, significant differences between the groups in both the baseline levels and in the net prolactin response to methadone. The depressive disorder patients stood out by having a significantly lower mean basal prolactin level ($p < 0.05$) than was observed in the other three groups of subjects. Further, the depressed patients had significantly lower mean levels in both 30 ($p < 0.01$) and 60 ($p = 0.01$) minute samples as compared to the schizophrenic, manic, and normal groups who responded to methadone with a much more marked and robust increase in prolactin.

An examination of the raw data revealed that eight of sixteen (50%) of the depressed patients had absent or very attentuated prolactin responses to methadone, while the remaining eight manifested prolactin increases. When a blunted prolactin response was defined by a rise of less than 2 ng/ml in either 30 or 60 minute samples, then eight depressed patients and two normals had blunted responses.

The mean growth hormone levels for the four experimental groups are presented in Table 2. As can be seen, methadone significantly increased the mean growth hormone levels in all four groups of subjects over baseline levels. It rose from a mean of 3.02 ± 1.34 mIU/ml at baseline to a high of 20.55 ± 9.66 mIU/ml at 60 minutes ($F = 12.03$; df = 40; $p < 0.05$). Although no

Table 1

Mean Serum Prolactin Levels (Ng/Ml) at Baseline, 30, and 60 Minutes Post-methadone (10 Mg) in the Three Psychiatric Patient and the Normal Control Groups

	Baseline	30 minutes	60 minutes	Δ Baseline to 60 minutes
Schizophrenics ($N = 8$)	15.9 ± 3.6	33.1 ± 9.4	42.0 ± 10.9	26.1
Manics ($N = 6$)	13.0 ± 4.5	30.8 ± 12.9	34.4 ± 13.5	21.4
Depressed ($N = 16$)	7.5 ± 0.9	10.6 ± 1.9	15.4 ± 3.5	7.9
Controls ($N = 11$)	14.1 ± 3.2	25.5 ± 6.3	30.6 ± 7.7	16.5
Mean for Entire Subject Sample	11.7 ± 1.5	21.9 ± 5.0	27.5 ± 5.3	15.8

Kruskal-Wallis One-Way ANOVA

Group Difference at Baseline	$H = 10.09$; df 3; $p < 0.05$
Group Difference at 30 Minutes	$H = 12.7$; df 3; $p < 0.01$
Group Difference at 60 Minutes	$H = 10.6$; df 3; $p < 0.01$

statistically significant differences emerged in growth hormone response in regard to diagnosis, there was evidence that the manic and depressed patients responded to methadone with a less marked increase in growth hormone in the 30- and 60-minute serum samples than did the schizophrenic and normal control groups. An examination of the raw data revealed that ten of thirteen depressed patients and five of seven manic patients had blunted growth hormone responses to the methadone challenge. However, three of seven patients in the schizophrenic and four of eleven in the control group also had blunted growth hormone responses. Thus, the blunted growth hormone responses did not occur as exclusively among the depressive disorder patients as was seen with the blunted prolactin response.

Eleven of the thirteen depressed patients for whom both growth hormone and prolactin data were available manifested either a blunted prolactin or growth hormone response or both to the same methadone challenge.

Discussion

Before discussing the data, which were derived under these experimental conditions, there are some issues potentially affecting the data which should be mentioned. One manic and two schizophrenic patients required single p.r.n. (as needed) doses of phenothiazine during the time they were on "drug-free" status. This slightly increased the baseline prolactin levels in these three patients, which in turn had an effect on the mean basal levels for the experimental groups of which they were members. There are reports that attenuated prolactin responses have been observed in subjects who are relatively hyperprolactinemic, but this was not manifested in these three patients, since each had robust prolactin increases following the methadone administration.

Another issue deserving of comment is the fact that the age range in the control group was lower and therefore not comparable to the three patient groups. This is an acknowledged flaw in the design, but on the other hand this should not affect the results presented here. Specifically, there is no evidence that age per se, at least within the range studied here (i.e., 21-54 years), would have any effect on either basal levels or upon the response to challenge agents of prolactin or growth hormone.

The mean basal prolactin level in the depressed patients was significantly lower than it was for the manic, schizophrenic, and control groups. Because the p.r.n. phenothiazine administration slightly increased the mean basal prolactin levels in the manic and schizophrenic groups, it is not our intention to highlight this particular finding, other than to mention that it is consistent with the reports by Asnis et al. (1980) and Linkowski et al. (1980), both of whom reported lower basal levels in depression. The blunted prolactin response to methadone we observed in eight of sixteen depressed patients is consistent with the findings of Linkowski et al. (1980) and Extein et al. (1980) who observed the same response from the challenges of TRH and morphine, respectively.

Table 2

Effect of Methadone-HCl (10 Mg Im) on Growth Hormone (mIU/Ml) in Psychiatric Patients and Normal Controls

	Baseline	30 Minutes	60 Minutes
Schizophrenics (*N* = 7)	2.53 ± 0.51	17.60 ± 14.10	46.29 ± 25.43
Manics (*N* = 7)	3.18 ± 0.89	6.17 ± 3.86	9.43 ± 5.40
Depressed (*N* = 13)	4.60 ± 2.90	4.19 ± 1.49	11.36 ± 5.43
Normals (*N* = 11)	2.09 ± 0.53	21.11 ± 9.96	22.15 ± 7.48
Mean for Entire Subject Sample	3.02 ± 1.34	12.46 ± 4.29	20.55 ± 9.66

Kruskal-Wallis One-Way ANOVA

Group Difference at Baseline	N.S.
Group Difference at 30 Minutes	N.S.
Group Difference at 60 Minutes	N.S.

There is clear evidence that methadone significantly increased the mean growth hormone secretion in the entire subject sample. Whereas there are reports in the literature indicating that opiate/opioids stimulate growth hormone secretion in animals (Meites et al. 1979; Shaar et al. 1977; Koenig et al. 1980), this is the first report of which we are aware reporting an opiate-induced growth hormone rise in normal subjects and in psychiatric patients. There were no significant group differences in the mean growth hormone response following methadone. Blunted growth hormone responses were present in subpopulations in each of the three patient groups and in the normal controls as well. Of specific interest was the fact that the majority of the patients in both the manic (five of seven) and the depressed (ten of thirteen) groups had blunted growth hormone responses to methadone. While the blunted growth hormone response did not occur exclusively in the affective disorder patients, it was predominantly manifested in these patients.

It is intriguing that eleven of the thirteen depressed patients, on whom we have both prolactin and growth hormone data, manifested blunting of prolactin or growth hormone or both to the same opiate challenge.

It is possible that the blunted prolactin and/or growth hormone response may be an additional neuroendocrine dysfunction that is correlated with the presence of affective disorder (e.g., depressive disorders). It is also possible that this neuroendocrine dysfunction may prove to be a useful diagnostic marker for the identification of this group of psychiatric disorders.

These findings are consistent with our original hypothesis that a potentially important interrelationship exists between the opioid peptide systems, certain neuroendocrine regulatory factors, and the pathophysiology of affective disorders. The exploration and characterization of this relationship continues to be a promising direction for future research.

Response of Plasma Cortisol and β-Endorphin Immunoreactivity to Surgical Stress

David Pickar, M.D.,[1] Martin R. Cohen, M.D.,[1] Michel Dubois, M.D.,[2] and William E. Bunney, Jr., M.D.[3]

Introduction

Considerable data now exist from animal experimentation that the endogenous opioid system plays an important role in the biological response to stress and in endogenous analgesic mechanisms (Amir et al. 1980; Rossier et al. 1980; Madden et al. 1977). Several lines of evidence support the notion that the endogenous opioid system is involved in pain perception in humans. Stimulation of the periaqueductal gray area in chronic pain patients has been shown to produce both analgesia and increased CSF levels of opioids (Hosobuchi 1977; Akil et al. 1978), while profound and long-lasting analgesia has resulted from the intrathecal administration of β-endorphin (Oyama et al. 1980). Naloxone-reversible stress-induced analgesia has recently been demonstrated to occur clinically (Willer et al. 1981). The relationship between stress and behaviors such as pain perception are, however, complex (Antelman & Cagguilla 1980) and biologic responses are known to vary with stress paradigm (Mason 1975) and with individuals (Naber et al. 1981).

The authors have used general surgery as a paradigm for studying stress effects on circulating levels of plasma β-endorphin immunoreactivity and cortisol in humans and for investigating relationships between pain perception and hormone levels.

Method

Nine adults (seven males, two females; ages 18-60) who underwent laparotomies as part of a National Cancer Institute protocol for the assessment of testicular or ovarian malignancy were studied. Patients were medication-free for at least 72 hours prior to surgery and were free of medical complications other than regional malignancy. Pre-medication was with pentobarbital (100 mg, i.m.) and anesthesia was induced with thiopental and muscle relaxant. No opiates were given until the 1st-3rd postoperative hour when the patient was awake, at which time morphine sulfate (1.5-3.5 mg/hr i.v.) was administered as needed (patient request) for relief of postoperative pain.

Plasma was collected from each patient prior to intubation and anesthetic induction, 10 minutes after skin incision, and at 30-minute intervals during surgery until skin closure. In six of the nine patients plasma was also collected immediately after intubation and during the period of postoperative morphine administration. Plasma assay for β-endorphin included antiserum prepared from rabbits against synthetic human β-endorphin and demonstrates by weight <50 percent cross-reactivity with β-lipotropin, <0.01 percent with α-endorphin and α-MSH, <0.004 percent with leu- and met-enkephalin and <5 percent with ACTH.

Results

Anesthesia induction did not significantly effect either plasma β-endorphin (ir) or plasma cortisol: pre-induction means ± SEM were 20.5 ± 2.9 pmole/liter and 23.7 ± 2.5 μg percent and post-induction means ± SEM were 26.9 pmole/liter and 26.1 ± 4.2 μg percent, respectively. In contrast, surgery was associated with significant increases in both variables (Figure 1). These elevated levels typically persisted throughout the surgical procedure and, in some patients, plasma β-endorphin (ir) increased still further upon awakening from anesthesia. Morphine administration was associated with significant decreases in both plasma cortisol and β-endorphin (ir) (Figure 2).

The authors used the total amount of morphine administered over the first 24 postoperative hours as an objective assessment of the degree of subjects, postoperative pain. Total morphine requirement was related to patient age ($r = -.69$, $p < .05$) and patient weight ($r = .55$, $p < .1$), findings consistent with known morphine pharmacokinetics. Neither age nor weight, however, were significantly related to mean surgery levels of β-endorphin (ir) (Table). Mean surgery levels of plasma β-endorphin (ir) were negatively correlated with total morphine requirement (Figure 3), while those of plasma cortisol showed a similar tendency ($r = -.65$, $p < .1$). Presurgery cortisol levels were significantly related to mean surgery cortisol levels ($r = .85$, $p < .01$).

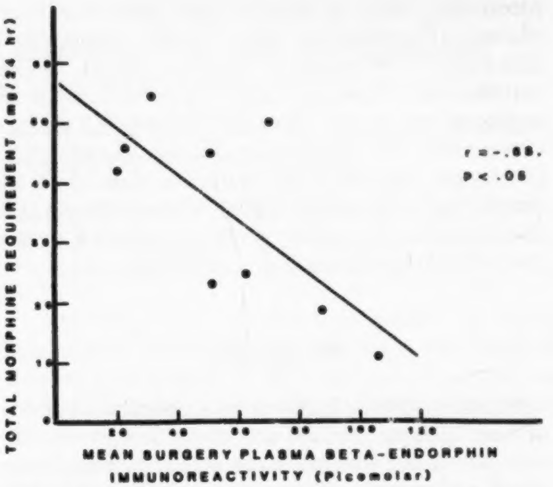

FIGURE 3. Correlation between mean surgery levels of plasma β-endorphin (ir) and total amount of morphine administered during the first 24 postoperative hours (1.5-3.5 mg/hr, i.v.)

Table

Patient Demography, Levels of Plasma β-Endorphin Immunoreactivity, and Post-Operative Morphine Requirements

Patient No.	Age	Weight (kgs)	Pre-surgery β-endorphin (ir) (picomolar)	Mean Surgery β-endorphin (ir) (picomolar)	Morphine Requirement* (mg/24 hr)
1	21	75.4	< 14.4	62.4	24
2	30	72.5	< 14.4	22.5	46
3	41	62.7	31.0	91.1	18
4	59	57.5	28.2	45.0	22
5	60	47.5	32.6	103.7	12
6	16	67.3	16.0	76.2	50
7	21	63.0	< 14.4	30.4	56
8	28	81.0	< 14.4	17.4	44
9	43	85.5	< 14.4	45.0	45

*mg per 1st 24 post-operative hours

Age vs Morphine Requirement: $r = -.69$, $p < .05$

Weight vs Morphine Requirement: $r = .55$, $p < .1$

Mean Surgery Plasma β-endorphin (ir) vs Morphine Requirement: $r = -.68$, $p < .05$

Because plasma β-endorphin (ir) levels prior to surgery were often lower than the sensitivity of our assay, no parametric testing of a correlation between these levels and postsurgical morphine requirement could be made. It was possible, however, to divide the patients into groups on the basis of data distribution (Table): six patients with low plasma β-endorphin (ir) levels (< 17 picomolar) prior to surgery and three with high plasma β-endorphin (ir) (≥28 picomolar). Similarly, morphine requirements were distributed biomodally: high requirements, 44-56 mg, and low requirements, 12-24 mg. All six patients with low presurgery plasma β-endorphin (ir) levels required high morphine doses and all three patients with high levels of plasma β-endorphin (ir) required low morphine doses ($p < .05$, Fisher Exact Test, two-tailed).

Discussion

Surgical stress proved to be a potent stimulator of both plasma cortisol and β-endorphin (ir). In contrast to the surgical stress itself, plasma levels of β-endorphin (ir) and cortisol were not significantly effected by anesthesia induction. Although this latter finding lends little support for an involvement of the endogenous opioid system in anesthesia effects, it does not exclude a role for brain opioids, whose contents have been shown to vary independently from pituitary β-endophrin (Rossier et al. 1977), or for other circulating opioids, in the mediation of anesthetic effects. The parallel cortisol and β-endorphin (ir) increases during surgical stress also support the close association between β-endorphin (ir) and the hypothalamic-pituitary-adrenal (HPA) axis (Mains et al. 1977; Guillemin et al. 1977; Vale et al. 1981). The marked decrease in both cortisol and β-endorphin (ir) associated with postoperative morphine administration suggests the possibility of a common feedback inhibition by opiates. It is also possible, however, that decreases in these neurohormones may relate to decreased conscious pain perception produced by morphine.

The wide individual differences in subjects, postoperative morphine requirements are consistent with clinical belief. This variance was in part explained by pharmacokinetic considerations such as relationships with age and body weight, and by non-pharmacokinetic variables such as plasma levels of β-endorphin (ir). Multiple regression analysis of patient age and mean surgery plasma β-endorphin (ir) increased the degree of variance predicted to 70 percent. Age and mean surgery plasma β-endorphin (ir) were individually able to predict 46 and 48 percent, respectively. Although this increase in variance predicted did not reach statistical significance, it does suggest the possibility that age and plasma β-endorphin (ir) may relate independently to postoperative morphine requirement.

The similar, although not quite as strong, negative correlation between stress-induced cortisol levels and postoperative morphine requirement may support a hypothesized link between human arousal and analgesia. Furthermore, the negative relationship between plasma β-endorphin (ir) prior to surgery and postoperative morphine usage suggests that variability in physical trauma may not be the major determinant of variance in postoperative pain. Rather, the patient's physiological response or arousal prior to surgery, which may be dependent upon the intensity of psychological stress and/or simply the innate responsiveness of the patient's arousal systems, seems to be a major determinant of postoperative analgesic requirement and may also predict the degree of physiological response to surgical stress.

Although levels of plasma β-endorphin (ir) are in actuality a composite of levels of β-endorphin and β-lipotropin, the results suggested that this complex may relate to important physiological processes. It is doubtful, however, that the plasma levels detected are, in and of themselves, sufficient to produce significant analgesia. More likely, these levels of circulating plasma β-endorphin (ir) reflect a central nervous system arousal which may involve the endogenous opioid system.

Elevated Plasma β-Endorphin Concentrations in Depression and Cholinergically Supersensitive Release Mechanisms[1]

S. Craig Risch, M.D.,[2] David S. Janowsky, M.D.,[2] Lewis L. Judd, M.D.,[2] and Leighton Y. Huey, M.D.[2]

Morning plasma concentrations of beta-endorphin immunoreactivity were significantly higher in a group of depressed patients meeting the Research Diagnostic Criteria for Major Depressive Disorder or Schizoaffective Disorder, depressed, than in age- and sex-matched groups of normal controls and psychiatric patients without affective disorders. Furthermore, physostigmine stimulated release of beta-endorphin immunoreactivity was also significantly greater in the depressed patients. These results provide the first evidence for elevated plasma concentration of beta-endorphin in depression and also represent further evidence for cholinergic supersensitivity in depression. These results suggest that elevated plasma concentrations of beta-endorphin and cholinergically stimulated hypothalamic-pituitary beta-endorphin release, might potentially represent biological state or trait markers for depression.

Introduction

Adrenal cortisol hypersecretion, as well as flattened cortisol circadian periodicity, and failure to suppress plasma cortisol concentrations with the overnight low-dose dexamethasone suppression test, occur in a significant number of endogenously depressed patients, and have now been well established as substantive neuroendocrine markers highly specific for primary affective disorders (Stokes et al. 1975; Brown 1979; Carroll et al. 1976a, 1976b, 1981; Sachar 1976; Sachar et al. 1980a; Schlesser et al. 1980). Many investigators also believe that this neuroendocrine abnormality reflects limbic-hypothalamic-

[2] Department of Psychiatry, School of Medicine, University of California at San Diego and San Diego Veterans Administration Medical Center, San Diego, CA 92161.

hypophyseal hyperactivity. In this regard, Fang et al. (1981), comparing pre- and post-dexamethasone plasma adrenocorticotropic hormone (ACTH) concentrations in cortisol-hypersecreting dexamethasone-resistant depressed patients and in normal controls, failed to detect any differences between the two groups in plasma ACTH concentrations, either before or after the standard 1.0 mg dexamethasone suppression test. However, Reus et al. (1980) have recently reported that although dexamethasone-resistant depressed patients did not differ statistically from dexamethasone-sensitive depressed patients in predexamethasone plasma ACTH concentrations, the dexamethasone-resistant depressed patients did have significantly higher post-dexamethasone plasma ACTH concentrations than did the dexamethasone-sensitive patients. Most recently, Kalin et al. (1982) have reported that dexamethasone-resistant patients have significantly higher pre- and post-dexamethasone plasma ACTH concentrations than do dexamethasone-sensitive patients. Obviously more studies are needed, but, to date, two of three investigations suggest that cortisol hypersecretion and dexamethasone resistance in depressed patients may be accompanied by elevated ACTH plasma concentrations.

Abnormalities in central noradrenergic (Sachar et al. 1980b), serotonergic (Carroll et al. 1979), and cholinergic (Carroll et al. 1979) neurotransmitter functions have all been mechanistically implicated in the pathophysiology of the presumed limbic-hypothalamic-pituitary-adrenal (CRF-ACTH-cortisol) hypersecretion in depression. With respect to central cholinergic mechanisms, substantial evidence from *in vitro* (Bradbury et al. 1975; Edwardson & Bennett 1974) and *in vivo* animal (Endroczi et al. 1963; Suzuki et al. 1964; Otsuka 1966; Naumenko 1968; Krieger & Krieger 1970; Balfour et al. 1975; Suzuki et al. 1975) and human (Cozanitis 1974; Hill & Wynder 1974; Davis & Davis 1980; Janowsky et al. 1980) investigations suggest that cholinergic agonists may activate the hypothalamic-hypophyseal-adrenal axis to increase cortisol secretion. In addition, Carroll et al. (1979) have demonstrated that dexamethasone resistance can be induced in normal subjects by infusions of physostigmine, an acetylcholinesterase inhibitor with both nicotinic and muscarinic properties. That cholinergic mechanisms might be significantly implicated was suggested by the fact that pretreatment of the subjects with atropine abolished this response. Also administration of ipecac, a potent stimulator of nausea and vomiting, failed to induce dexamethasone resistance, suggesting that this effect may not simply reflect "nonspecific stress."

If central cholinergic mechanisms are involved in the pathophysiology of cortisol hypersecretion in depression, and if the observed elevated plasma cortisol concentrations reflect on increased hypophyseal secretion of ACTH, then it might be hypothesized that plasma beta-endorphin concentrations might also be elevated. In fact, we have recently demonstrated that ACTH and beta-endorphin are co-released in humans under conditions of central cholinergic stimulation (Risch et al., in press). These results parallel the original observations of Guillemin et al. (1977) and others (Pellefier et al., 1977; Rossier et al. 1977) in animal stress paradigms.

An abnormality in acetylcholine neurotransmitter function has also been implicated in depression. Janowsky et al. (1972) have hypothesized that acetylcholine may play an important role in the pathophysiology of affective disorders, and more recently have demonstrated that affective disorder patients are both behaviorally and neuroendocrinologically supersensitive to the effects of physostigmine when compared with nonaffective disorder patients (Janowsky et al. 1980; Risch et al. 1981). Also, Sitaram et al. (1980) have suggested that affective disorder patients may be supersensitive to central cholinergic induction of rapid-eye-movement (REM) sleep, possibly reflecting a generalized cholinergic receptor supersensitivity in depression. Thus a cholinergically regulated hypothalamic-hypophyseal ACTH-beta-endorphin axis might also be cholinergically supersensitive in affective disorder patients.

Method

These studies were conducted under the Food and Drug Administration's approved Investigational New Drug application and with local human subjects committee approval. All subjects gave written informed consent. All subjects were male and there was no significant difference in age composition among experimental and control groups. To be included, subjects had to be off medication for at least 2 weeks prior to participating in the studies. All subjects received a Research Diagnostic Criteria (RDC) diagnosis based on a Schedule of Affective Disorder and Schizophrenia interview by an experienced diagnostician and collateral information obtained from previous hospitalizations, medical records, and interviews with family members.

Plasma samples for basal morning plasma beta-endorphin immunoreactivty concentrations in the subject groups were obtained as follows. On two separate days, varying between 3 and 7 days apart, an 18-gauge heparin lock catheter was inserted at 8 a.m. in a forearm vein for subsequent plasma sampling. After an accommodation period of 30 minutes, three plasma samples were drawn at 15-minute intervals for subsequent beta-endorphin determinations. The beta-endorphin values from these six samples were averaged to give a mean morning plasma beta-endorphin concentration for each subject.

Differences in cholinergically stimulated hypothalamic-pitutary plasma beta-endorphin concentrations among individuals were determined as follows. After an 8 a.m. insertion of an indwelling heparin-lock venous catheter and subsequent plasma samplings as described above, each subject received methscopolamine 1.0 mg intramuscularly 20 minutes prior to physostigmine or placebo infusions to induce partial peripheral cholinergic blockage. Each individual received infusions of physotigmine salicylate (22 μg/kg) and placebo (sterile saline), 100 cc infused over 10 minutes, in a randomized, double-blind, counter balanced paradigm. Physostigmine and placebo infusions were separated by 3 to 7 days. Plasma samples were obtained from the indwelling venous heparin lock catheters at 10, 20, 30, 45, and 60 minutes subsequent to the physostigmine and placebo infusions. The average of the three baseline pre-infusion plasma beta-endorphin concentrations was subtracted from peak post-infusion plasma beta-endorphin concentrations, to determine each individual's physostigmine and placebo associated increase in plasma beta-endorphin immunoreactivity concentrations.

Four subject groups were compared with respect to: 1) basal morning plasma beta-endorphin concentrations and 2) cholinergically stimulated hypothalamic-hypophyseal plasma beta-endorphin increases. The composition of the groups was SADS/RDC: normals, $N=12$; major depressive disorder (unipolar 6, bipolar 6), $N=12$; nonaffective disorder psychiatric patients, $N=6$; and schizoaffective disorder, depressed, $N=4$.

Significance of changes in plasma beta-endorphin immunoreactivity was determined by repeated measures analysis of variance. Significance of differences among groups in basal plasma beta-endorphin immunoreactivity concentrations and in cholinergically stimulated plasma beta-endorphin immunoreactivity concentrations were determined by one-way analysis of variance and subsequent Scheffé's S Method analysis to compare specific groups.

Plasma beta-endorphin concentrations were measured by radioimmunoassay as previously reported (Risch et al. 1980). The antibody for beta-endorphin has a 50 percent cross-reactivity with beta-lipotropin but less than 0.1 percent with alpha-endorphin and alpha-melanocyte-stimulating hormone, and less than 0.004 percent with leucine and methionine enkephalin. Within assay variability for beta-endorphin is approximately 5 percent and between assay variability is approximately 9 percent. Sensitivity varies from 25-50 pg/ml.

Results

Morning basal plasma beta-endorphin immunoreactivity concentrations were significantly elevated in patients with major depressive illness (123 ± 9.5 pg/ml) and schizoaffective disorder, depressed (131 ± 11.3 pg/ml) as compared with normal subjects (65 ± 6.6 pg/ml) and patients without major affective illnesses (61 ± 4.6 pg/ml): $F(3,30) = 16.2$; $p<0.0001$ (*see* Figure 1). There was no statistically significant difference in basal plasma beta-endorphin immunoreactivity concentrations between patients with major depressive illness and schizoaffective illness, depressed.

In each group, physostigmine infusions resulted in significant increases in plasma beta-endorphin immunoreactivity concentrations as compared to placebo infusion, in agreement with similar results previously reported (Risch et al. 1980). Physostigmine associated increases in plasma beta-endorphin immunoreactivity concentrations were significantly higher in patients with major depressive illness (143 ± 19.4 pg/ml) and schizoaffective disorder (287 ± 51 pg/ml) as compared with normal subjects (73 ± 21 pg/ml) or psychiatric patients without affective illnesses (57 ± 25 pg/ml): F (3,30) = 10.5; $p < 0.0001$ (*see* Figure 2). Physostigmine associated increases in plasma beta-endorphin immunoreactivity concentrations were significantly higher in the schizoaffective group than in the major depressive disorder group, $p < 0.01$, (Scheffé's "S" A Posteriori Method).

Discussion

These findings represent the first report suggesting that plasma concentrations of beta-endorphin, like ACTH and cortisol, may be elevated in depressed subjects, possibly reflective of limbic-hypothalamic-hypophyseal hyperactivity. These results parallel the observation of Terenius et al. (1977) of elevated cerebrospinal fluid "Fraction I" endorphins in severely depressed patients, although presumably cerebrospinal fluid endorphins derived from arcuate nucleus projections to the third ventricle, while the plasma endorphins observed in this study originate from the anterior pituitary. The significance of elevated plasma beta-endorphin concentrations in depressed subjects is unclear. The elevated beta-endorphin concentrations could conceivably be of mechanistic significance in the etiology of the depressed state, or might result as a consequence of the depressed state. Further experimental studies will be necessary to discern the role of elevated plasma endorphin concentrations in depression.

These differences in basal plasma beta-endorphin concentrations among the different nosological groups confound the interpretation of the observed differences in physostigmine asssociated plasma beta-endorphin increases in these same groups. However, the observed enhanced responsivity of the depressed patients, as measured by absolute change scores, is at least consistent with the

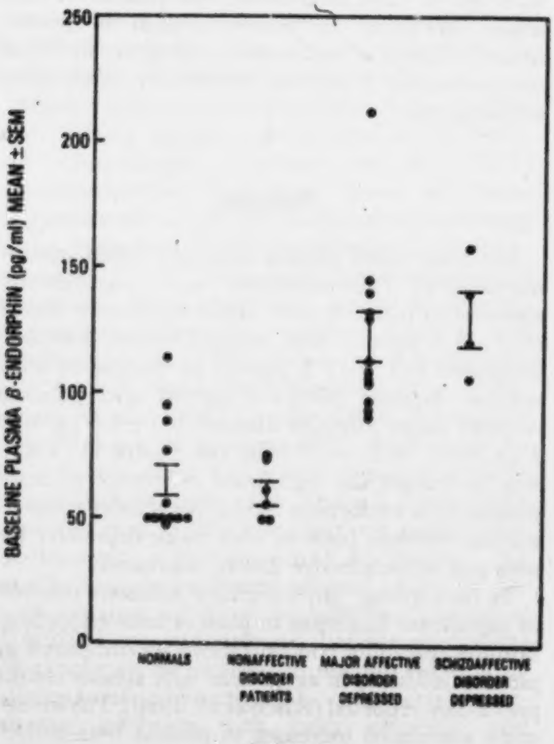

FIGURE 1

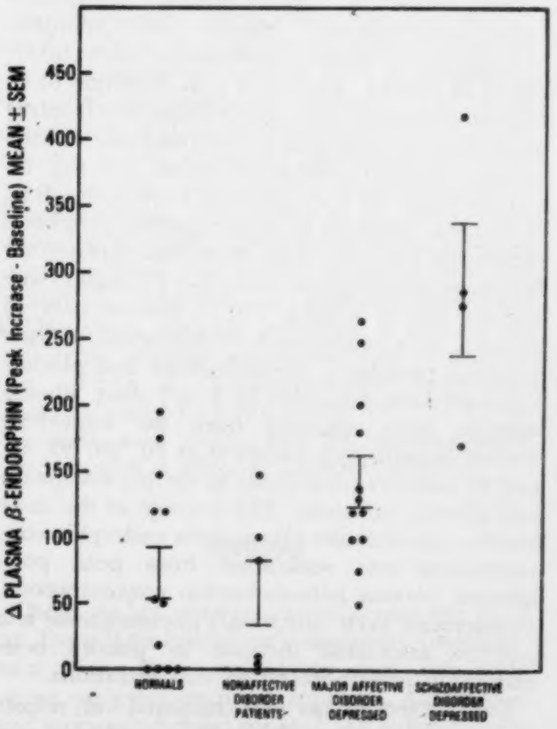

FIGURE 2

possibility of a hypersensitivity of the hypothalamic-hypophyseal beta-endorphin axis to central cholinergic stimulation in depressed patients. These findings add further support for the possibility of cholinergic supersensitivity in affective disorders (Janowsky et al. 1973, 1980; Risch et al. 1981) and parallel the findings of Sitaram and coworkers (1980) of apparent supersensitivity of affective disorder patients to central cholinergic induction of REM sleep. These findings are consistent with the possibility, as suggested by Carroll and colleagues (1979), that central cholinergic hyperactivity could be of mechanistic significance in the elevated plasma concentrations of ACTH and cortisol (and beta-endorphin in this study) observed in depressed patients.

Finally, if the elevated plasma beta-endorphin concentrations and the enhanced release of beta-endorphin in response to physostigmine are specific for depressed patients, beta-endorphin could represent a potential biological state or trait marker for depression.

Endorphins May Be Involved in the Behavioral Response to Dextro-Amphetamine[1]

Uriel Halbreich, M.D.,[2] Susanna Goldstein, M.D.,[2] Ee-Sing Lo, Ph.D.,[3] and Jean Endicott, Ph.D.[4]

Halbreich et al. (1981a), reported that normal postmenopausal women had a dysphoric response to intravenously administered 0.15 mg/kg dextroamphetamine—a dose that usually causes elation and increased activity in normal young men. This finding has been confirmed by the investigators in a second group of subjects, and may provide a model for the study of the mechanism of the mood and behavioral responses to amphetamine.

Both normal postmenopausal women and normal young men have an increase in plasma levels of cortisol in response to the drug (Halbreich et al. 1981b). Postmenopausal women have a blunted growth hormone response (Halbreich et al. 1980) and they do not show an increase of plasma levels of prolactin (PRL) in response to amphetamine, while PRL levels of young men are increased in response to the same stimulus (Halbreich et al. 1981c). The hormonal responses were also confirmed in the second group of subjects.

Even though some correlations were reported between the baseline levels or the magnitude of change in levels of these hormones, and the behavioral response to amphetamine (Halbreich et al. 1981d; Nurnberger et al. 1981), the authors believe that these do not shed much light on the mechanism of the behavioral response to the drug. Some other mechanisms, compatible with previous findings, should be tested.

It has been proposed (Byck 1976; Belluzzi & Stein 1979) that an excess of endorphins may be involved in euphoria, mania, and amphetamine-induced psychostimulation. There were some suggestions, including that of Gerner et al.

			b) No	10, 30	2
Dettmar et al. (1978)	mice	Locomotor activity	Yes	0.3, 1, 3	2
Haber et al. (1978)	rats	Rearing activity	Yes	10	1.5
Haber et al. (1978)	rats	Hyperactivity	No	10	1.5
Horita & Carino (1978)	rabbits	Analeptic effect	Yes	2	0.5
Segal et al. (1979)	rats	1) Locomotor activity	Yes	0.5, 5, 10	0.5, 2.5
		2) Stereotypy	No	Up to 20	2.5
Rethy et al. (1971)	mice	Locomotor activity	No	10	1 - 10
Perez-Cruet et al. (1979)	rats	1) Locomotor activity	Yes	10	0.5, 2.5
		2) Stereotypy	No	10	0.5, 2.5
Adams et al. (1981)	rats	1) Locomotor activity	Yes	1, 2, 4	2.5 (5, 10)
		2) Stereotypy	No (Potentiated)	1, 2, 4	2.5 (5, 10)

(1980), that levels of endorphins may be lower than normal in depression.

These assumptions are far from being established and, at best, they are too simplistic. However, at least in the case of amphetamine, there is some evidence that opioid mechanisms may be involved or may even modulate the behavioral response to the drug. Several groups (those listed in the Table, and a review by Sawynok et al. 1979) reported that the administration of the opioid antagonist naloxone abolished behavioral response to amphetamine in animals. It seems that this interaction is dose-dependent and probably also species-dependent. This is mainly suggested in view of reports from laboratories where different species were tested with different doses (Dettmar et al. 1978; Holtzman 1975). Furthermore, when naloxone was added to amphetamine, the dose-response curve of the later drug was shifted downward and not to the right as would be expected by a direct competition phenomenon. The downward shift may be the common endpoint achieved through a diversity of mechanisms, because other drugs can alter the dose-response curve of amphetamine for operant behavior and locomotor activity in a manner similar to naloxone (Reviews: Weiss & Laties 1969; Rech & Stolk 1970) but naloxone is unique in that it has no influence on these activities when administered alone.

The involvement of opioid mechanisms with human behavioral response to amphetamine is unclear. It was reported by Cohen et al. (1981) that plasma levels of β-endorphin were increased following infusion of 0.3 mg/kg dextroamphetamine to eight normal monozygotic twins. The increase in levels of β-endorphin was significantly correlated ($r = 0.76$) to the increase in levels of cortisol. However, when amphetamine was administered to schizophrenic patients (Schulz et al. 1981), no increase in levels of β-endorphin was found. This finding, which confirmes previous reports concerning cortisol (Halbreich et al. 1981b), may point to an exclusion of β-endorphin as the opioid involved in the behavioral and mood response to amphetamine. Future studies should probably concentrate on other opioids, like met-enkephalin (Belluzzi & Stein 1977). Such studies should be facilitated once some technical obstacles in the radioimmunoassay of plasma methionine-enkephalin are overcome.

Endorphins also probably interact with, or modulate neurotransmitters and trace amines like phenylethylamine (PEA), whose involvement in the mechanisms of behavioral response to amphetamine has been strongly suggested by several groups (Reviews: Mosnaim & Wolf 1978).

PEA is a naturally occurring amine that mimics amphetamine in its behavioral effects. Amphetamine has been shown to markedly affect PEA levels in the central nervous system. In rabbits it reduces three times the brain content of PEA in the first 30 minutes. In mice and rats it has been shown to increase the turnover of PEA in the brain, markedly augment its synthesis, and accelerate its disposition. Depletion of brain PEA by pretreatment with α-methyldopahydrazine (AMDH) decreases many of the central actions of amphetamine. The time course of changes in stereotype and motor activity of untreated rats in response to PEA also is similar to that of amphetamine.

The role of PEA in the behavioral response to amphetamine has never been adequately demonstrated in humans. In any case, a multivariate approach should be applied to the study of the physiology of the behavioral and mood responses to amphetamine. In future studies an attempt should be made to integrate the various changes in many substances into a comprehensive picture.

Where Is the "Lesion" in Patients Who Fail to Suppress Plasma Cortisol Concentrations with Dexamethasone?[1]

Ned H. Kalin, M.D.,[2] Stephen J. Weller, M.D.,[2] William T. McKinney, M.D.,[2] Gary W. Kraemer, M.D.,[2] and Steven E. Shelton[2]

Introduction

The failure to suppress plasma cortisol concentrations after the low-dose dexamethasone suppression test (DST) occurs in up to 50 percent of patients with depressive illness (Brown et al. 1979; Carroll et al. 1981; Sachar et al. 1980; Schlesser et al. 1980). This endocrine abnormality has been studied extensively in psychiatric patients but little is known about its underlying pathophysiology. Using depressed subjects and nonhuman primates, the authors have begun to explore the factors mediating this dysfunction. The following studies were designed to further characterize the role pituitary adrenocorticotropic hormone (ACTH) secretion plays in mediating cortisol nonsuppression in depressed patients.

Materials and Method

Human Studies

Twenty-eight male inpatients, selected for clinical reasons to undergo a DST, were tested by the method of Carroll et al. (1981) within the first week of admission. An 8 a.m. baseline blood sample was drawn, and at 11 p.m. 1 mg of dexamethasone was administered orally. Blood samples were obtained at 8 a.m. and 4 p.m. the following day. Diagnostic and Statistical Manual-III (DSM-III) diagnoses were made from both patient interviews and chart reviews. Data from the human studies will be presented in greater detail in another report (Kalin et al., in press).

Patients were excluded from the study if they suffered from a life-threatening medical illness, poorly controlled diabetes mellitus, alcohol withdrawal, or disease involving the hypothalamic-pituitary-adrenal (HPA) system. Patients taking medications known to interfere with the DST (Kalin et al. 1981) were also excluded. Any patient with a postdexamethasone value of >5 μg/dl in either the 8 a.m. or 4 p.m. sample was considered a cortisol nonsuppressor.

Monkey Studies

The rhesus monkeys used in this study were housed in three peer groups, $N=4$, $N=4$, and $N=3$, and underwent repetitive peer separations as described by McKinney et al. (1972). At the end of the separation week a DST was performed on each animal Blood was drawn by femoral venipuncture at 9 a.m. on the day before and after the 11 p.m. intramuscular administration of dexamethasone sodium phosphate (150 μg/kg).

Blood Collection and RIAs

All blood samples were collected into glass tubes containing 10.5 mg of EDTA and were immediately placed on ice. The samples were then centrifuged for 10 minutes at 3,000 r.p.m. for the separation of plasma; plasma was frozen at −70°C until assayed.

In the human samples, plasma cortisol concentrations were assayed using an RIA kit supplied by Clinical Assays with a sensitivity of 2 μg/dl.

The monkey samples were measured with a kit supplied by New England Nuclear with a sensitivity of 1 µg/dl.

ACTH immunoreactivity was assayed using an RIA kit obtained from Immunonuclear Corp. (Risch et al., in press) with a sensitivity of 37.5 pg/ml, and intraassay variability of ± 10 percent. Samples from human and monkey experiments were assayed separately in one run.

Results

Human ACTH Concentrations

The patients were separated into two groups on the basis of their cortisol response. The suppressors ($N = 17$) consisted of nine patients meeting criteria for major depressive episode and eight patients meeting criteria for other DSM-III diagnoses. The nonsuppressors ($N = 11$) all met criteria for either major depressive episode or bipolar depression. The Table demonstrates that the mean plasma ACTH concentration in the nonsuppressor group was significantly higher than in the suppressors both before and after dexamethasone administration. In the 8 a.m. predexamethasone samples the nonsuppressors' mean ACTH concentration was 93.9 ± 26.16 pg/ml compared to 51.1 ± 6.47 pg/ml in the suppressors ($t = 1.91$, $p < 0.05$, one-tailed t-test). The 8 a.m. postdexamethasone mean ACTH concentration was also significantly greater in nonsuppressors, 83.9 ± 25.80 pg/ml compared to the suppressors' 45.5 ± 5.20 ($t = 1.79$, $p < 0.05$, one-tailed t-test).

Table

Mean Plasma ACTH (pg/ml ± S.E.M.)

	Suppressors ($N = 17$)	Nonsuppressors ($N = 11$)	One-Tailed t-Test
8 a.m. Predexamethasone	51.1 ± 6.47*	93.9 ± 26.16**	$t = 1.91$ $p < 0.05$
8 a.m. Postdexamethasone	45.5 ± 5.20	83.9 ± 25.80	$t = 1.79$ $p < 0.05$
4 p.m. Postdexamethasone	58.4 ± 5.65	76.9 ± 20.05	$t = 1.06$ N.S.

* 8/17 of the suppressors were < 37.5 pg/ml
** 3/11 of the nonsuppressors were < 37.5 pg/ml

Monkey ACTH Concentrations

The Figure demonstrates the ACTH and cortisol concentrations for the 11 rhesus monkeys at the end of their separation week. In the monkeys cortisol nonsuppression was defined as a 9 a.m. postdexamethasone concentration of > 10 µg/dl. Baseline ACTH concentrations were greater in the monkey cortisol nonsuppressors compared to the suppressors. However, this difference did not reach statistical significance. Postdexamethasone ACTH concentrations were similar in cortisol suppressors and nonsuppressors, but the postdexamethasone cortisol concentrations varied significantly.

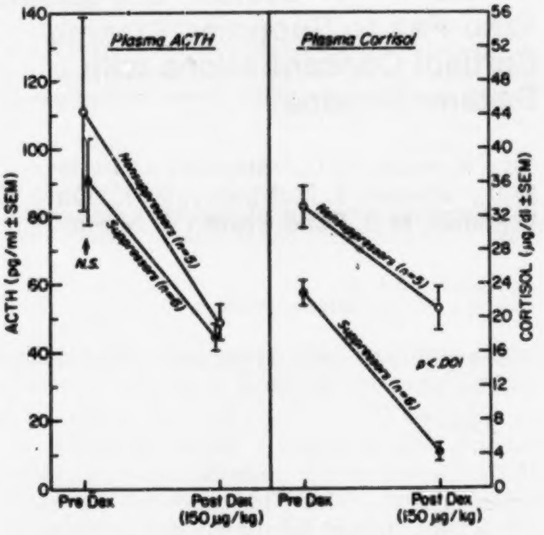

FIGURE. The mean plasma ACTH and cortisol concentrations for 11 rhesus monkeys after peer separation. Cortisol nonsuppression was defined as a postdexamethasone concentration of > 10 µg/dl.

Discussion

Since it has been demonstrated that changing plasma cortisol concentrations are not always directly related to pituitary ACTH secretion (Krieger & Allen 1975; Holaday et al. 1977; Risch et al. in press), it cannot be assumed that the cortisol abnormalities seen in depressed patients reflect hypothalamic and/or pituitary dysfunction.

The authors found that plasma ACTH concentrations are significantly greater in human cortisol nonsuppressors than in suppressors at 8 a.m. before and after dexamethasone administration. The actual differences between the two groups may be even greater than our data show, since 3/11 of the nonsuppressors and 8/17 of the suppressors had predexamethasone ACTH concentrations below the sensitivity of our RIA. In monkeys, baseline ACTH concentrations also tended to be greater in the cortisol nonsuppressors, but postdexamethasone ACTH concentrations did not vary between the suppressors and nonsuppressors as in humans. The similarity in the baseline ACTH concentrations between monkeys and humans supports our earlier suggestion that the rhesus monkey is a reasonable model to use in exploring the regulatory mechanisms of the hypothalamic-pituitary-adrenal system in humans (Kalin et al. 1981).

ACTH concentrations in depressed subjects' have been reported in only two other studies. Fang et al. (1981) found essentially no differences among 8 a.m. predexamethasone ACTH concentrations in normals, depressed cortisol suppressors, and depressed nonsuppressors. They also found no differences at 8 a.m. after dexamethasone; however, ACTH concentrations were significantly greater in their nonsuppressor group at 4 p.m. postdexamethasone.

In a preliminary report Reus et al. (1982) found significantly greater ACTH concentrations after dexamethasone administration in depressed cortisol nonsuppressors compared to depressed suppressors. They also reported a trend for higher predexamethasone 8 a.m. ACTH concentrations in the nonsuppressors compared to the suppressors. The Reus et al. study (1982), as well as the authors' findings, support the hypothesis that the failure to suppress plasma cortisol concentrations after dexamethasone is related to increased pituitary ACTH secretion.

An Epidemiologic Perspective on Senile Dementia—Facts and Fragments

Jacob A. Brody, M.D.,[1] and Lon R. White, M.D., M.P.H.[1]

In 1978 there were 2.5 million Americans 85 years and older. By the year 2000 there will be between 3.3 and 6.7 million people 85 and older in this country, depending upon mortality trends. In this age group the estimated prevalence of dementia exceeds 20 percent. The tragedy and the staggering burden represented by this illness and attendant disability is broadly appreciated.

The characteristic pathologic changes of Alzheimer's disease occur in both its senile and presenile forms. Although multi-infarct dementia (MID) accounts for 20 to 40 percent of the dementias of late life, not all patients have either definite MID or the characteristic neuropathologic changes of Alzheimer's disease (Terry 1978). To further confuse matters, these changes are found so frequently among the elderly (dying of all causes) as to raise the question whether senile dementia of the Alzheimer's type (SDAT) is a disease at all or a part of normal aging. Also unclear is the relationship to these conditions of the entity that Kral refers to as benign scenescent forgetfulness (Kral 1978). It can be persuasively argued that pre-senile Alzheimer's disease and SDAT should be considered one disease entity whose vistims range in age from middle to late life. However, a failure to discriminate pre-senile from senile dementia may obscure true differences in pathogenesis if in fact they are not the same disease. The problem of disease definition illustrated by this observation is probably in part responsible for the failure of clear epidemiologic patterns or discernible risk factors to have emerged from previous research efforts.

Although biochemical and anatomic differences between the brains of patients with SDAT and those of patients dying of unrelated conditions have been and continue to be the subject of elegant research efforts, no clear understanding of pathogenesis exists. Epidemiologists have thus far contributed little to the resolution of the problem, since the only factor definitely associated with increased risk is advanced age. Despite this, age-specific incidence and prevalence curves have not been clearly defined. Such definition would contribute to the determination of whether or not SDAT has a unitary pathogenesis, and to the development of measures of frequency for the comparison of individuals grouped according to characteristics or exposures. The methodologic problems most responsible for this paucity of information involve: a) the need to study entire communities of elderly persons, b) the need for a standardized and valid means of classifying individuals according to cognitive ability/disability, and c) for incidence studies, the need for repeated observations over a period of years. These problems are also responsible for uncertainty as to the effect of dementia on life expectancy as it may be modified by the age of onset of the illness.

Prevalence rates for SDAT throughout the world do not vary greatly. Approximately 4 percent of the population over 65 has what can be called a malignant form of senile dementia, with about 20 percent having a mild form of cognitive disability. As mentioned, the prevalence rises sharply with age to approximately 20 percent with severe dementia at age 80 (Mortimer et al. 1981). A general conformity has been noted for data derived from population surveys and to some extent from regional institutional surveys.

Clinicians tend to agree that there are more women than men with SDAT. Electroencephalographic findings over time, however, suggest that fast wave activity is better preserved in females than in males (Busse & Obrist 1963). The female excess may be the result of greater longevity, greater likelihood of seeking medical attention, or greater likelihood of being widowed and living alone, hence requiring institutionalization more frequently than would a male.

Although differences by race have not been reported, confidence in the lack of a difference in dementia incidence between black and white elderly persons is limited because of marked differences in survival. The apparent absence of differences in incidence according to race and sex may be interpreted as suggesting that the pathogenesis of senile dementia may not involve those characteristics and factors known to be associated with differential mortality by sex and race.

Professional pugilists represent the only occupational group which seems to be predisposed to dementia, an observation which has thus far led to no insights into the etiology of SDAT.

A neurologic disease which includes dementia is responsible for approximately 10 percent of adult deaths among the Chamorro people of Guam. Although this syndrome, Parkinsonism-dementia of Gual, shares several neuropathologic characterists with SDAT, its pathogenesis remains as obscure as that of SDAT despite many years of vigorous investigation (Brody et al. 1975). No other geographic or ethnic focus of SDAT is known, except for foci related to familial Alzheimer's disease.

The sporadic form of dementia accounts for the vast majority of SDAT cases. Interest in the familial form relates to the implications of the conclusion that the disease can have a genetic causation (Goudsmit et al. 1981). Thus far these implications have led to no greater understanding of the causes of sporadic SDAT, but have served to guide and encourage avenues of research which consider genetic contributions to pathogenesis. Preliminary findings suggested that familial Alzheimer's disease was transmissible to primates by intracerebral innoculation, and thereby resembled the transmissible spongiform encephalopathies, Kuru and Creutzfeldt-Jacob disease. This appears not to be the case, and the balance of evidence fails to support a slow virus etiology (Goudsmit et al. 1980).

No history of earlier life exposure, rural or urban residence, medical illness, or psychiatric condition appears to predispose to the development of senile dementia. A reported increased risk among persons of lower social status is of uncertain significance, since test batteries used to detect dementia certainly discriminate against such persons and since socioeconomic factors might modify the likelihood that a person would come to medical attention (Gurland 1981).

None of the variables mentioned above has been studied by comparing age-specific prevalence or incidence curves. Instead, most were analyzed by examining age adjusted rates or by comparing the frequency of the variable among SDAT patients with that in the general population or in a control group. Nevertheless, the absence of obvious clustering or of clear differences in risk according to these several factors argues against specific exposures (such as to zoonotic agents or aluminum in antacids) as important etiologic factors.

Although epidemiologic studies have unearthed no patterns of disease occurrence which point to definitive pathogeneses, there are two fascinating, not yet fully substantiated, observations. The first is an association with increased familial frequency of Down's syndrome. This observation is made more exciting by the report that the neuropathologic changes of Alzheimer's disease apparently occur in all (or nearly all) Down's syndrome patients who live to be 40 (Heston & Mastri 1977). The second and less well substantiated observation is of advanced maternal age at the time of birth of individuals who eventually develop SDAT (Cohen & Eisdorfer 1981). It appears that this association may hold for some but not for all groups of SDAT patients, since it was not substantiated by another study in which birth order was investigated as a possible risk factor (Akesson 1969).

It may be meaningful that the risk of SDAT, a condition occurring much more commonly among the very old, seems so unaffected by factors differentially related to longevity. Perhaps this suggests that we should direct our attention away from the sort of adult characteristics, life style, and exposure factors which seem to be involved in determining who survives to be old-old, and toward genetic, early life, and late life characteristics and exposures. The alternative view is that the failure to define risk factors has been due to aggregation of cases of heterogeneous pathogenesis (but clinical similarity) or that the methods of factor and/or endpoint definition have been imprecise or inappropriate.

The epidemiologic data most immediately needed involve the age-specific prevalence, incidence, and clinical course of dementia in medically unselected, longitudinally studied populations of elderly persons. There is also an obvious need for research approaches in which correlations are sought between epidemiologic, neuropsychologic, biochemical, clinical, and pathologic observations. Such studies should reflect the recent burgeoning of information relative to cognitive function evaluation and neurotransmitter metabolism (particularly as related to the cholinergic system), and to hypotheses based on biochemical and neuropathological observations. Careful attention should be give to genetic indicators, including the frequency among family members of other conditions (Down's syndrome, leukemia, immune dyscrasias, or certain neurological diseases), and certain genetic markers (especially HLA markers such as the DB7-CW3 Haplotype, and the HP^1 haptoglobin gene product) (Eisdorfer et al. 1980; Walford & Hudge 1980; Stam & Op den Velde 1978). A different approach would involve the in-depth study of kindreds afflicted with familial Alzheimer's disease or sharing an increased risk for the sporadic form of dementia.

It is essential that, while responding to new knowledge generated by clinical and laboratory studies, the epidemiologist bring to bear on the problem of dementia his most rigorous and imaginative methodologies in the hope of accomplishing: 1) the identification of factors associated with either increased or decreased risk for developing dementia, or 2) the delineation of patterns (i.e., disease occurrence, severity, clinical expression, course) which would point to differentiation of groups of dementia patients having different pathogeneses.

Workshop—

Antipsychotics and Clinical Response: An Overview

John M. Davis, M.D.,[1] Katherin Hendricks, B.S.,[1] and Javaid I. Javaid, Ph.D.[1]

There have been very few methodologically appropriate investigations of the relationship between antipsychotic drug concentrations in plasma and clinical efficacy. One of the complicating matters is that in chronic schizophrenics who show very little symptomatology (so called "burned-out" schizoprenics) it is often difficult to rate improvement. Curry and Marshall (1968) first noted that there were marked individual differences in plasma levels among schizophrenic patients on comparable doses of chlorpromazine. A range of almost 20-fold difference (approximately 25 to 500 ng/ml) in plasma levels was seen in patients on reasonable clinical doses. A few patients who had very low levels of chlorpromazine failed to show side effects or clinical response. One patient with a high chlorpromazine plasma level showed excessive sedation. When the dose was lowered, plasma levels decreased, and this patient showed a clinical response. It is necessary that these exploratory open studies be verified by properly controlled studies.

Sakalis et al. (1972) treated a small number of schizophrenics and manics with 300 mg of chlorpromazine daily. Since they deliberately included patients who were not acutely ill (because they chose patients amenable to psychophysiological studies), it may have been an inappropriate sample to study for therapeutic effects. Lader (1976) extended the study to include a larger group of new patients, many of whom were acutely ill. However, 300 mg is probably lower than the ED_{50} dose of chlorpromazine (the average dose necessary to produce 50 percent of maximal improvement). For this reason, it would be very unlikely that any patient would have plasma levels above the therapeutic window. The expected relationship between plasma level and clinical efficacy would, therefore, be a linear one at this dose. In a recent report of results on the first 32 patients, the investigators found a correlation of -0.32 between clinical efficacy and plasma levels, which is of borderline significance ($p = 0.4$ level, one-tailed).

Wode-Helgodt et al. (1978) did a methodologically valid study on patients who were treated with randomly assigned fixed doses of 200, 400, or 600 mgs of chlorpromazine per day. In 15 male schizophrenics, there was a positive correlation ($r = 0.82$, $p < 0.01$) between improvement and prolactin elevation at 4 weeks. There was a similar correlation between plasma levels and clinical response. May et al. (1981) studied schizophrenic patients generally treated with chlorpromazine (6.6 mg/kg/day) for 28 days. Plasma chlorpromazine and prolactin levels did not correlate with the clinical outcome.

Chlorpromazine can theoretically be metabolized to 168 different metabolites. It is known that many metabolites of chlorpromazine have pharmacological activity. If a chemical assay measures only the unchanged chlorpromazine, and if the clinical effects are produced to a fair extent by metabolites, and if the amount of metabolite is not well correlated with the amount of unchanged drug, then the presence of active metabolites may obscure the correlation between chlorpromazine-plasma levels and therapeutic efficacy. This may complicate the interpretation of chlorpromazine studies.

Other Antipsychotics

Cotes et al. (1978) treated patients with a fixed dose of flupenthixol and noted a correlation between prolactin levels and total symptom changes ($r = 0.56$, $p < 0.05$).

In 29 schizophrenic patients plasma fluphenazine levels had an inverted U-shaped relationship with clinical response (Dysken et al. 1981). Most nonresponders have either very low fluphenazine levels or very high fluphenazine levels. Also patients treated with haloperidol showed an inverted U-shaped relationship (unpublished results). Nonresponders have either very low plasma haloperidol or very high haloperidol levels.

Use of Free or RBC Levels

It is the concentration of free drug which is in equilibrium with tissue drug levels. Quantification of free drug is technically impossible at this time, yet potentially quite important. Drugs must cross the blood-brain barrier to reach central receptor sites. These factors of distribution, in addition to rate of metabolism, will determine the amount of drug at receptor site. If some of the mechanisms involved in the drug's distribution across the cell membrane of the red blood cell mimic those governing the passage of drug through the blood brain barrier, then drug levels within RBC (or RBC/plasma ratio) may give additional information. In fact, Manian et al. (1974) have shown similarities between RBC and rat brain synaptosomes-chlorpromazine levels. If the assumption is valid, then RBCs may be a preferred tissue for drug measurement.

Garver et al. (1976) administered butaperazine on a constant dose schedule to acutely symptomatic schizophrenic patients while measuring plasma and RBC levels. Although both plasma and RBC levels vs. response were best characterized by an inverted U-shaped curve, the relationship using RBC levels was more striking. These results support the hypothesis that RBC levels of antipsychotic drugs are a better correlate of clinical response and side effects than plasma levels. These results have been replicated in a completely new sample of patients (Casper et al. 1980).

Blood Levels in Chronic Schizophrenics

Most schizophrenics respond to some degree to neuroleptic drugs and then return home. However, there are occasional patients who show no response to drugs whatsoever and need to be hospitalized in a chronic state hospital. Since some of these very chronic patients are fast metabolizers, failure to respond to drugs might be a possible explanation of their chronicity. Such a chronic population was found to have their plasma and red cell levels substantially below those seen in the acute population (Smith et al. 1979). A similar, very unresponsive group of patients in an acute setting was also studied. Many of these patients had absolutely no clinical response to antipsychotic drugs; many were, indeed, considered for transfer to a chronic facility. In essence, this was the same population as the chronic nonresponders, but identified in an acute setting. These patient also had extremely low plasma and red cell levels. A fair number of these nonresponders did respond when given higher than normal doses of fluphenazine enanthate or decanoate. Since chlorpromazine undergoes first-pass metabolism, an intermuscular formulation may bypass this first-pass effect to achieve an adequate plasma level.

Conclusion

Although all studies do not agree, it appears from the literature that in general, antipsychotics may have a range of drug concentration. Below and above this range the clinical response appears to be less. Measuring blood levels has added an important dimension in treating schizophrenic patients. However, there is a need for more controlled, methodologically valid studies.

Measurement of Antipsychotics in Patients

Javaid I. Javaid, Ph.D.,[1] Robert D. Linden, M.D.,[1] and John J. Davis, M.D.[1]

It is well established that patients treated with similar doses of antidepressants or antipsychotics have pronounced variations of drug concentrations in plasma (Alexanderson 1972; Forsman et al. 1977; Garver et al. 1977; Hammer & Sjoqvist 1967; Javaid et al. 1981). These interindividual differences have emphasized the need for measuring drug concentrations in blood and correlating these with clinical effects. A number of controlled studies with various antidepressants, have demonstrated a significant relationship between antidepressant concentration in plasma and clinical response. This information, particularly for nortriptyline, imipramine, and lithium, can be used as a guideline for antidepressant concentration in plasma in patients being treated with these medications. The therapeutic or toxic concentrations for most of the antipsychotics, however, have not been established. This scarcity of information has, in part, been due to the lack of specific and sensitive methods for measuring low therapeutic levels of high potency antipsychotics. In recent years, however, there has been emphasis on the development of such methods and at present sensitive and specific methods are becoming available.

In the present studies, drug concentrations in plasma from patients treated with different antipsychotics were measured by gas liquid chromatographic (GLC) methods and radioreceptor assay (RRA). The RRA is based upon the assumption that the therapeutic action of antipsychotic drugs is mediated through their ability to block dopamine receptors. The radiolabeled neuroleptics (such as [^{3}H]-spiroperidol) bound to specific membrane receptors can be displaced by compounds binding to the same receptors. Since RRA measures the total pharmacological activity of the sample *in vitro*, it has great potential for clinical efficacy studies. Potentially, RRA may be used to measure all antipsychotics of different chemical structures in the same assay, expressing the results as "activity units" against one standard (such as chlorpromazine or haloperidol).

Table 1

Neuroleptic Levels by Chemical and Radioreceptor Assays

Drug	*N*	GLC	RRA	*r*	RRA Chem
		ng/ml			
Butaperazine	10	152.0	201.0	0.84*	1.3
Haloperidol	20	7.2	10.1	0.62**	1.3
Fluphenazine	20	0.97	7.1	0.85†	7.3
Trifluoperazine	35	0.7	5.7	0.02	8.1

* $p < 0.05$
** $p < 0.01$
† $p < 0.001$

The drug concentrations in plasma from patients treated with four different antipsychotics are shown in Table 1. The parent compounds were used as standards for both the GLC and RRA. The similar values obtained by both methods for butaperazine (RRA/GLC ratio = 1.3) and haloperidol (RRA/GLC ratio = 1.3) suggest that most likely these drugs do not have many active metabolites *in vivo*. On the other hand, RRA values for both fluphenazine and trifluoperazine were 7-8 times greater than the drug concentrations measured by GLC. Higher values by RRA indicate the presence of active metabolites which were not measured by GLC method.

---

[1] Illinois State Psychiatric Institute, Chicago, IL 60612.

Since the RRA measures the total inhibitory activity in the sample, theoretically this would be an advantage in clinical efficacy studies, where the investigator is primarily concerned with the clinical effects of the drug, which may be due to the parent drug and/or the active metabolites. It has been shown that *in vitro* potencies of different antipsychotics in blocking dopamine receptors are linearly correlated to their daily doses required for therapeutic treatment in patients (Seeman & Lee 1975). If a certain degree of dopamine blockade is required for the amelioration of schizophrenic symptoms, then the *in vitro* differences of potencies between antipsychotics could account for the differences in clinical doses. Since RRA measures total dopamine blockade activity, one would expect that at therapeutic doses, all antipsychotics would produce similar dopamine blockade activity. However, this was found not to be true. Table 2 shows that the dopamine blockade activity in plasma samples from patients treated with high potency antipsychotics (haloperidol, perphenazine, fluphenazine, and trifluoperazine) was much smaller than butaperazine and thioridazine. Similar results have been reported by other investigators (Calil et al. 1979; Cohen et al. 1980). One possible explanation for large differences in the dopamine receptor blockade activity (as determined by RRA) in plasma from patients treated with different antipsychotics, may be that some of the active metabolites do not cross blood brain barrier. Another possibility is that the binding affinities of different neuroleptics and their metabolites to plasma proteins may vary widely.

Table 2

Neuroleptic Concentrations (CPZ - Equivalence) In Patients Treated with Therapeutic Doses

Drug	Neuroleptic Activity (Chlorpromazine Equivalence)
Thioridazine	1,974
Butaperazine	1,196
Haloperidol	66
Perphenazine	44
Fluphenazine	71
Trifluoperazine	62

The chemical assays (such as GLC) for antipsychotics require sample extraction and are time-consuming; however, they are specific. On the other hand, RRA and radioimmunoassays (RIA) for antipsychotics do not require any extraction, are simple and expedient. These methods, however, are not specific. It has been shown (Rubin et al. 1980) that antibodies prepared against haloperidol by two different methods had different cross reactivities and gave different values of haloperidol in the same samples. Hence, the choice of the method depends upon the specific aims of the investigator, and the methodological details should be kept in mind.

The *Psychopharmacology Bulletin* is prepared by the Pharmacologic and Somatic Treatments Research Branch of the National Institute of Mental Health. Its purpose is to facilitate the dissemination and exchange of information among the national and international scientific community. The emphasis is on rapid, informal reporting of work which has not appeared in the more formal literature. We invite contributions such as original articles, brief reports, review articles, letters to the Editor, news items, books for review, and announcements appropriate for the *Bulletin*.

All material published in the *Psychopharmacology Bulletin* is in the public domain unless otherwise noted. Publication in the *Bulletin* therefore does not preclude publication elsewhere.

Individuals interested in submitting material to the *Psychopharmacology Bulletin* should contact:

Allen Raskin, Ph.D.
Editor-in-Chief
Psychopharmacology Bulletin
National Institute of Mental Health
5600 Fishers Lane Rm. 10C-14
Rockville, MD 20857

We respectfully ask you to adhere to the following guidelines when preparing a paper for the *Psychopharmacology Bulletin:*

1. Manuscript Format: Manuscripts should be typed double-spaced with ample margins, and submitted in triplicate. Do not split paragraphs from one page to another, even if this makes page lengths uneven. Also, do not hyphenate words at the end of a line, even if this makes uneven lines.

Title page should include each author's name, degree, and full address.

Papers should be written in *third* person, e.g., the investigators found, **Not:** I found, we found. Contents should be *substantive,* not indicative, e.g., the investigator used the gas chromatography method to determine the three molecular structures, **Not:** The author described the method for determining the structure of the drug.

2. Figures: Figures, charts, or graphs should be submitted as glossies (photographs printed on smooth shiny paper) or should be professionally prepared using black ink on white paper. Only one copy is needed. Indicate in the text where these figures and their legends should be placed.

3. References: References mentioned in the text should appear as full citations in the **References** following the text with *all* authors cited in the reference list, e.g., Simpson, G.M., Lee, L.H., Zubok, B., and Gardos. A rating scale for tardive dyskinesia. *Psychopharmacology (Berlin),* 64(2): 171-179, 1979.

If a work has two authors, always cite both names every time the reference occurs in the text, e.g., (Swanson & Cole 1974). If more than two authors, cite only the surname of the first author in the text followed by et al., e.g., Williams et al. 1963.

4. Abbreviations: Abbreviations should appear in parentheses after the first time they are mentioned in the paper, i.e., Brief Psychiatric Rating Scale (BPRS).

Use generic names in referring to drugs; trade names may be given in parenthesis the first time a drug is mentioned only.

Journal titles should be abbreviated in the *References* according to the National Library of Medicine's Index Medicus.

5. Brief Reports: Authors wishing very rapid reporting of new work may submit manuscripts of up to five typed double-spaced pages for inclusion as Brief Reports. If accepted, these results would appear in the next issue of the *Bulletin*. In preparing a manuscript for publication as a Brief Report, please follow the format cited above.

Fellowship Program

The University of Texas Health Sciences Center announces the third year of their Clinical Psychopharmacology Fellowship Program for physicians who have completed psychiatric residency training. Two positions are open for the 1983-1984 year. The fellow will be eligible for an appointment as Instructor in the Department of Psychiatry and will receive a commensurate stipend.

The program inclues: a) clinical research experiences in several of the ongoing studies in the department; b) clinical psychopharmacological preceptorial work; c) participation in one of the ongoing studies of biological disturbances in major psychiatric illness; d) wet laboratory experience in analytical methods; e) an integrative tutorial series to provide an overview of neuropharmacology, biological hypotheses of psychiatric disorders, and clinical investigative techniques; f) participation in graduate school and other Health Science Center courses and seminars pertinent to the learning needs of the fellow; and g) opportunity to emphasize study and training in a selected clinical area.

For further information, please contact: Charles L. Bowden, M.D., Nancy U. Karren Professor of Psychiatry, Dept. of Psychiatry, The University of Texas Health Science Center at San Antonio, 7703 Floyd Curl Drive, San Antonio, TX 78284.

Meeting Announcements

The 1983 meeting of the **Society of Behavioral Medicine** will be held at the Hyatt Regency in Baltimore, Maryland on March 2-5, 1983. There will be a special track for the Fourth Annual Meeting on the topic of Behavioral Medicine in Industry. For further information, please contact: Thomas J. Coates, Ph.D., Program Chair, Society of Behavioral Medicine, P.O. Box 8530, University Station, Knoxville, TN 37996.

Announcement and call for papers for the VIIth World Congress of the **International College of Psychosomatic Medicine** to be held in Hamburg, Federal Republic of Germany, July 17-22, 1983. This Congress will take place immediately after the World Congress of Psychiatry in Vienna. Topics for the plenary session will be: early identification and prevention of psychosomatic disorders; maintaining health despite stress and adverse circumstances; the effectiveness of psychotherapy on specified psychosomatic disorders; integrational models of psychosomatic pathogenesis; taxonomic subgroups within psychosomatic diseases; the psychosomatic problems involved in somatic treatment; integration of psychosomatics into hospital treatment; and the influence of social change and economic factors on psychosomatic disorders.

Epidemiology, original points of view, theoretical viewpoints, pain, sleep and dreams, hypnosis, behavioral therapy, psychosomatic illness in the elderly, and various other topics will be discussed in the symposia.

For further information, contact Psychosomatics 83, Hamburg Messe und Congress GmbH, Congress Organization, P.O. Box 302360, D-2000 Hamburg 36, Federal Republic of Germany.

* * * * *

The **Canadian College of Neuropsychopharmacology** will be holding its Sixth Annual Scientific Meeting in Saskatoon, Saskatchewan on May 25-28, 1983. The sponsors are various departments of the University of Saskatchewan. The meeting will include an academic lecture by the 1982 Heinz Lehmann award winner, Dr. T. L. Sourkes; plenary lectures; symposia; roundtables; workshops; oral communications; and poster sessions.

For further information, please write to 1983

CCNP Meeting, c/o Psychiatric Research Division, University Hospital, Saskatoon, Saskatchewan S7N OXO, Canada.

* * * * *

The Second International Congress on Drugs and Alcohol will be held December 18-22, 1983 in Tel-Aviv, Israel. This multidisciplinary congress is being organized by the Society for Medicine and Law in Israel and the Israel Medical Association, and will provide an excellent opportunity for researchers, intervention agents, and policymakers to exchange their views, concerns, and future plans.

Those interested should contact: Congress Secretariat, Peltours Ltd., Congress Department, P.O. Box 394, Tel Aviv, 61003 Israel.

Book Reviews

- **The Psychobiology of Affective Disorders,** edited by Joseph Mendels, M.D. and Jay D. Amsterdam, M.D., presents the proceedings of a symposium held in February 1980. The symposium gathered a group of experts to review current knowledge of psychobiologic factors associated with clinical depression. The presentations and discussions focused on biological factors in the etiology of depression and as predictors of differential response to psychopharmacologic treatment.

The 14 papers presented represent a wide range of research efforts and attempt to summarize relevant data on the interaction of specific factors as neurotransmitters, receptors, hormones, and genes with the psychologic and environmental components of depression. The volume expresses an optimistic view that significant progress is being achieved in understanding the psychobiology of affective disorders. Although considerable research is required to fully understand the complexities of this problem, the contributors are encouraged that this psychobiological avenue of investigation has great potential for the development of a rational approach for the diagnosis and therapy of affective disorders.

In the opening chapter, Martin Katz discusses the epidemiology of depression and explanations for its apparent increasing incidence, including increased awareness of its presence. Next, David Dummer presents recent clinical, biologic, and genetic data supporting the subclassification of affective disorders into unipolar, bipolar I, and bipolar II subtypes.

Elliot Gershon's paper reviews the evidence that genetic factors are of importance in determining vulnerability to major affective disorder. The usefulness of information about affective disorders in first-degree relatives for treatment and prevention of these disorders is presented.

Three chapters by James Maas and Yung Huang, Jay Amsterdam and Joseph Mendels, and David Janowsky provide an in-depth review of noradrenergic, serotonergic, and cholinergic neuronal system functioning and depression. Alan Fraser and Joseph Mendels focus on evidence that repeated administration of antidepressant drugs leads to compensatory neuronal processes that modify the initial effects of an enhanced noradrenergic response. Each of these contributions skillfully delineates the currently conceptualized role of these neurotransmitters in the complex regulation of affect and the pathophysiology of affective disorders.

The theoretical and clinical significance of the neuroendocrine aspects of depression is presented by Bernard Carroll. Carroll describes the utility of the dexamethasone suppression test (DST) as a measure of neuroendocrine disinhibition. About 50 percent of endogenously depressed patients show this phenomenon.

In Boyd Hartman's presentation, depression is conceptualized as one component of a dysregulation of general central homeostatic mechanisms. This research indicates that tricyclic antidepressants have pharmacologic effects on cerebral vascular permeability mediated by the central adrenergic regulatory system. Thus, he believes these drugs may have biologically important central effects on non-neuronal tissues.

In two additional chapters, recent pharmacologic and clinical studies and sleep and circadian rhythm disturbance in depression are reviewed by David Hawkins. In the concluding three chapters, George Winokur, Morris Lipton, and Jay Amsterdam and Joe Mendels discuss the advances in clinical psychiatric practice resulting from psychiatric research, and attempt to summarize new psychobiological strategies in affective illness.

This book is valuable as an wide-ranging review of the psychobiology of affective disorders. Generally, the contributions are concise, readable, and informative reviews of past and current work in the area. Several of the authors present provocative new theories and hypotheses. The inclusion of the open discussion following each presentation provides additional perspectives on the topic. The book contains valuable information and extensive references for both clinicians and psychopharmacologic researchers.

The book may be ordered directly from the publisher, S. Karger, Basel, Switzerland. Price: SFr. 39./DM47./U.S. $23.50. 220 pp. soft cover.

• **The Missing Link,** by Walter J. Garre, is a philosophical and psychological attempt to explain the "transition from animal instinct to the human mind." The main result of this transition, Dr. Garre states, is man's sense of self-glory. All human motivation stems from this need to feel important, resulting in unrealistic rationalizations and beliefs about other humans and nature. Included are the beliefs that man can control nature, that mankind has a specific purpose, and that there is a God who is aware of the existence of each individual.

The one recurring theme in this book is that of strict determinism. Each human being is physically and emotionally the product of his genetic endowment and environmental experiences. Free will is an unrealistic creation to enable the individual to feel special.

Dr. Garre attempts to explain a wide range of topics through his deterministic theory. Some of these topics are evolution, personality disorders, depression, violence, anxiety, sexual disorders, love, and art. Most personality traits, claims Garre, arise as a result of the degree of acceptance and importance felt by the child in early years. The reader is continuously reminded, however, that the parents themselves are only as adequate as their parents prepared them to be.

The Missing Link is a thorough discussion of determinism. It also serves as a primer on Darwinian theory as well as Freudian and Jungian theories of personality. Unfortunately, this book does not provide any insights on the transition from animal instincts to the human mind, as the title claims. It does discuss the differences or lack of differences between humans and animals. The book also does not provide "scientific proof," as the author states, of his theory. Rather, Dr. Garre explains contradictions between determinism and various twin studies by pointing out the inadequacies of the studies cited; he does not provide evidence, scientific or otherwise, to substantiate his beliefs.

Despite its shortcomings, the book does make interesting and, at times, provocative reading.

The book may be ordered directly from Philosophical Library, 200 West 57th Street, New York, NY 10019. Price:$15.00; 293 pp.

• **Compendium of Current Source Materials for Drugs,** compiled by Eutychia Londos, is an annotated bibliography of sources where librarians, health professionals, and interested lay persons can find information on drugs. The 12 sections of this text include the following types of materials: standard reference books for both prescription and nonprescription drugs; dictionaries and encyclopedias; evaluative and comparative sources; sources for laws and regulations, including names and addresses of national and international enforcement agencies; books and pamphlets for general reading, including alcoholism, drug abuse, and drug therapy; directories of education information; treatment centers and agencies, with national information centers for smoking listed; bibliographies on drug sources; journal and newsletters; reports; audiovisual catalogs and indexes, including names and addresses of pharmaceutical companies providing free loan film services; and computers and on-line databases, annotating the most recent developments in this new area of drug information retrieval. A combined author and title index is provided.

The author, Eutychia Londos, is a librarian working primarily with audiovisual materials and computerized literature retrieval services. Updates or supplements to this compendium are planned as new source materials become available.

The book may be ordered directly from the publisher, Scarecrow Press, Inc., 52 Liberty Street, P.O. Box 656, Metuchen, N.J. 08840. Price: U.S. $12.50; 146 pp. Size: 8 1/2 x 11.

New Journal

Clinical Gerontologist, a new journal in the field of aging and mental health, edited by T.L. Brink, Ph.D., is now being published by The Haworth Press, Inc., 28 East 22nd Street, New York, NY 10010. The Journal is written and refereed by and for mental health practitioners. The editor is interested in topics such as organic brain syndrome, depression, paranoia, hypochondriases, psychosomatic disorders, suicide, multidisciplinary teams, alcoholism in later life, and helping families of dependent elders.

New Books

- **The Handbook of Biological Psychiatry.** Edited by Prof. Dr. Herman van Praag, Malcolm Lader, Ole Rafaelsen, and Edward Sachar. Individual titles are: Disciplines Relevant to Biological Psychiatry; Brain Mechanisms and Abnormal Behavior (Psychophysiology); Brain Mechanisms and Abnormal Behavior (Genetics and Neuroendocrinology); Brain Mechanisms and Abnormal Behavior (Chemistry); Drug Treatment in Psychiatry-Psychotropic Drugs; and Practical Applications of Psychotropic Drugs and Other Biological Treatments. The books can be purchased individually or in a set. The entire set price (6 volumes) is $370.75 (Twenty percent higher outside the U.S. and Canada). New York: Marcel Dekker, Inc., 270 Madison Avenue, New York, NY 10016.

Lithium and Manic Depression: A Guide. Written by John Bohn, R.Ph. and James Jefferson, M.D., with assistance from other staff members at the Lithium Information Center, Department of Psychiatry, University of Wisconsin-Madison, 600 Highland Avenue, Madison, WI 53792. Price: $3.00 per copy (1 to 10 copies); $2.00 per copy (more than 10 copies).

Notice

Use of Approved Drugs of Unlabeled Indications*

The appropriateness or the legality of prescribing approved drugs for uses not included in their official labeling is sometimes a cause of concern and confusion among practitioners.

Under the Federal Food, Drug, and Cosmetic (FD&C) Act, a drug approved for marketing may be labeled, promoted, and advertised by the manufacturer only for those uses for which the drug's safety and affectiveness have been established and which FDA has approved. These are commonly referred to as "approved uses." This means that adequate and well-controlled clinical trials have documented these uses, and the results of the trials have been reviewed and approved by FDA.

The FD&C Act does not, however, limit the manner in which a physician may use an approved drug. Once a product has been approved for marketing, a physician may prescribe it for uses or in treatment regimens of patient populations that are not included in approved labeling. Such "unapproved" or, more precisely, "unlabeled" uses may be appropriate and rational in certain circumstances and may, in fact, reflect approaches to drug therapy that have been extensively reported in medical literature.

The term "unapproved uses" is, to some extent, misleading. It includes a variety of situations ranging from unstudied to thoroughly investigated drug uses. Valid new uses for drugs already on the market are often first discovered through serendipitous observations and therapeutic innovations, subsequently confirmed by well-planned and executed clinical investigations. Before such advances can be added to the approved labeling, however, data substantiating the effectiveness of a new use or regimen must be submitted by the manufacturer to FDA for evaluation. This may take time and, without the initiative of the drug manufacturer whose produce is involved, may never occur. For that reason, accepted medical practice often includes drug use that is not reflected in approved drug labeling.

With respect to its role in medical practice, the package insert is informational only. FDA tries to assure that prescription drug information in the package insert accurately and fully reflects that data on safety and effectiveness on which drug approval is based.

Adverse Drug Reactions

Safe Passage (How Good a Guarantee?)

Paul Leber, M.D.

In the author's first three contributions to this column, he examined aspects of two alleged causal relationships between drug exposure and untoward events (lithium and leukemia; neuroleptics and sudden death), and the more general problem of common untoward clinical events falsely attributed to drug exposure.

In this column, the author will address another class of problem which is frequently encountered in the process of conducting drug safety assessments. What is the significance of failing to detect any untoward events during drug exposure? In other words, what conclusions may be drawn from a report of "safe passage?"

Clearly, safe passage by several persons on a particular voyage does not guarantee that all travelers will be kept out of harm's way on similar trips. Any assurance that can be drawn from reports of safe passage must be qualified by a consideration of how many individuals have attempted the voyage, and the qualities and character of those who enjoyed safe passage.

Consideration of each of these caveats is especially critical when a report of "safe passage" is likely to lead to an increased use of a potentially toxic drug in what may be called a "physiologically disadvantaged" population.

A case in point is a recent and reassuring *New England Journal of Medicine* article on the apparent safe use of two tricyclic antidepressant drugs in ambulatory patients with heart disease (Veith et al. 1982). Before discussing the article and its relationship to safe passage, however, some background on the risks attributed to the use of tricyclics in patients with cardiovascular disease is necessary.

The cardiotoxic effects of large overdoses of tricyclics were recognized by 1959 (Mann et al.). Concern about the danger they may pose to cardiac patients (when used at therapeutic doses) can be traced to 1) a 1961 report of severe postural hypotension and associated myocardial infarctions (Muller et al.), and 2) a 1970 report of an increased incidence of sudden death (Coull et al.). Other evidence about tricyclics in heart disease, however, is more comforting. One widely quoted hospital based epidemiological survey by the Boston Collaborative Drug Surveillance Program (1972), for example, suggests that the short term outcome of hospitalized patients with "cardiovascular disease" was not affected by treatment with tricyclics. The usefulness of this report has been questioned, however. In the view of one of the preeminent groups in the field, the Boston study has many shortcomings and is not as reassuring as it may seem at first reading (Glassman & Bigger 1981). In particular, the study's sanguine outcome must be evaluated in light of the following information: 1) the average dose of tricyclic administered was below 81 mg per day, and 2) the mean observation period was 2 weeks or less for the two largest specific drug groups (amitriptyline and imipramine).

On the other hand, not all the evidence is negative: one of the pharmacologic properties of tricyclic drugs may offer protection to some patients with heart disease. Bigger and Glassman's

---

Note: This article was written by Dr. Leber in his private capacity. No official support or endorsement by the Food and Drug Administration is intended or should be inferred.

group have documented that the quinidine-like, anti-arrhythmic effect of imipramine may, under selected conditions, prove beneficial to the patient with heart disease (Bigger et al. 1977).

Given this background, the potential significance of the investigation by Veith and his colleagues can be readily understood. Clinicians are often confronted with significantly depressed patients who have serious heart disease. Aside from the dysphoria and suffering associated with the depressed state, depression may interfere with successful physical, social, and vocational rehabilitation of the patient. Thus, a direct examination of the risk of antidepressant drug use in depressed cardiac patients is an important undertaking which commands the interest of the medical community. When the results of such a study support the relative safety of antidepressants, one may anticipate a change in tricyclic use in clinical practice. Indeed, one may expect the influence of the article to be fairly widespread, given the large readership of the *New England Journal of Medicine.* In light of these considerations, it seems important to examine, critically, the message of safe passage conveyed in the article, be it explicitly intended by its authors or not.

The paper is entitled, "Cardiovascular Effects of Tricyclic Antidepressants in Depressed Patients with Chronic Heart Disease." Below the title, set in bold type, is the synopsis of the study which states, in part, "Our findings underscore the need for a reappraisal of the cardiovascular risks of tricyclic antidepressants and suggest that in the absence of severe impairment of myocardial performance, depressed patients with preexisting heart disease can be effectively treated with these agents without an adverse effect on ventricular rhythm or hemodynamic function." It seems possible that a reader may interpret this statement as a more or less unqualified endorsement of tricyclic use in heart disease.

Admittedly, the discussion section of the paper presents a more comprehensive analysis of the study's limitations. The authors note that their patient sample contained relatively few patients with seriously impaired cardiac performance (i.e., ejection fractions below 0.35). They comment that their paper cannot resolve that issue of the relationship between sudden death and tricyclics. Nevertheless, they are fairly sanguine about the safety of tricyclics in "patients considered at high risk for cardiovacular side effects. . ."

How was this conclusion reached in a study involving 17 drug-treated patients? More important, is the conclusion reasonable? A fair response to these questions must begin with a detailed examination of the study.

Twenty-four patients (outpatients?) from the psychiatric and medical services of the Seattle V.A. Medical Center took part in this double-blind, parallel-control design, clinical trial. All subjects were males with heart disease who were catagorized as suffering from "secondary major depressive disorder, endogenous subtype, according to research diagnostic criteria." All participants had scores of 18 or more on the 17-item Hamilton Depression Scale and had been depressed for a mean of 7 months prior to treatment. Twenty-three of the patients had had a previous myocardial infarction (none within 2 months of the study). Although no patients had "evidence of overt congestive heart failure," "many" were taking cardiac medications throughout the trial.

Patients were assigned to one of three treatment groups (imipramine, doxepin, or placebo) for a period of 4 weeks by a "modified randomization" procedure. Subjects were not stratified on measures of ventricular performance. Consequently, although the differences among the group means were not significant (small "n"?), four of the five subjects with the lowest baseline ejection fraction values were distributed to the placebo group. In characterizing the patient sample, it is important to note that only one of the eight imipramine recipients had an ejection fraction at rest of less than 0.40. Indeed, it appears that eight drug-treated patients had ventricular performance, at rest and upon exercise, which fell in the normal range (N.B., "appears" because the individual results can only be estimated by extrapolation from a graph.) Indeed, on average, the sickest patients were assigned to placebo (i.e., the mean duration of baseline exercise was significantly lower in the placebo than in the imipramine group).

Patients on active treatment were begun on 50 mg p.o., h.s., and advanced on an every 3-day fixed schedule to the maximum dose permitted by side effects. A maximum dose limitation of 150 mg that had been imposed initially was removed because of good experience with the first eight drug-treated patients. Dosage, however, was held constant in the last week of treatment in an attempt to reach steady-state conditions. At the end of week 4, plasma levels of imipramine ranged from 34 to 468 nanograms per ml (mean of 147) and plasma levels of doxepin ranged from 21 to 646 nanograms per ml (mean of 174).

The authors evaluated the patients over the course of the trial on several measures of depression and cardiac function. Put succinctly, the results showed that the drug-treated groups enjoyed a significant within-group improvement from their baseline depression assessments, and a two-way Analysis of Variance (ANOVA) demonstrated a significant (?overall) drug-placebo treatment difference.

The assessments of cardiac function did not reveal any adverse effect of antidepressant treatment. Specifically, there were no statistically significant changes in left ventricular function as measured by a change in the mean ventricular ejection fraction (CVEF) at rest or with exercise.*

Evidence of ventricular irritability based upon the number of premature ventricular contractions per hour was difficult to assess because of the very high within, subject variability observed between repeated observations. Estimates of cardiac electrical activity based upon weekly 12 lead EKG recordings (i.e., heart rate, PR interval, QRS interval, and corrected QT interval) also showed no clinically important differences between the groups.

Finally, recorded blood pressures did not identify a statistically significant change in the extent of orthostatic hypotension observed pre- and post-treatment in the three treatment groups. Nevertheless, it is important to note that postural dizziness associated with documented orthostatic hypotension did occur in one patient given imipramine and in three given doxepin. One patient on doxepin had a syncopal episode.

Returning to the original question posed by this author, given the results of the Veith study, can one reasonably conclude that it is "safe" to use tricyclics in depressed patients with cardiovascular disease?

The answer, of course, depends upon what one is willing to accept as evidence of "safety" for this particular indication and population. Clearly, because "safety" is an abstraction, safety can never be demonstrated directly. Instead, one estimates the risk of injury associated with drug exposure and equates the relative absence of risk with some degree of relative safety. Thus, for practical purposes, the drug safety assessment process is directed at making a reliable estimate of the incidence of untoward events in the population upon drug exposure. Then, based upon some undefined process, personal beliefs about the magnitude of the risk, the benefit of the drug's effect, and the gravity of the condition being treated, are integrated to reach a judgment about the drug's relative safety.

Viewed from this perspective, the value of the Veith study as a predictor of tricyclic safety depends upon the precision of the estimate of the risk of serious injury that can be obtained from its results.

Judged by these standards, the Veith study, involving merely 17 drug-treated patients, can be expected to detect only relatively common risks and to be rather imprecise in estimating the bounds of these risks. This should not be especially surprising, as large multicenter studies involving hundreds of patients are known to be relatively insensitive to untoward events that occur at frequencies below 2 or 3 percent. The limitation that a small sample size places on the ability to detect a significant risk can be illustrated for the sample size used in the Veith study, 17.

To make the argument clear, let us assume that the population actually contains two classes of individuals: 1) those who will and 2) those who will not come to grief if treated with tricyclics. Given this assumption, how large a proportion of the depressed cardiac patient population might be at risk despite the safe passage of the 17 individuals observed in Seattle?

This question can be answered using the binomial distribution as a model. The question is formally stated in the following manner. How large must "p," the proportion of subjects who will suffer harm, be to be 95 percent certain that at least one patient in a sample of 17 will suffer the event? If no events are observed in the sample of 17 patients, then we can be equally certain that the true proportion, "p," must be less than the one calculated. For the binomial distribution, the probability of detecting one or more events is unity minus the probability of detecting none in a sample of 17 individuals. Setting the probability of the statement at 95 percent, the equation can be solved for the value of "p": $[0.95 = 1-(1-p)^{17}]$. The calculated value of "p" is approximately 0.16. Thus, the failure of Veith and his colleagues to detect even a single instance of tricyclic-induced ventricular impairment among 17 patients can only be considered unlikely if more than 16 percent of the depressed cardiac population were going to suffer a serious impairment of ventricular performance when treated with tricyclics. This is not a very reassuring result regardless of one's vantage point.

---

*Ventricular ejection fraction (VEF) is now widely used as a measure of ventricular performance. The VEF is a dimensionless index, obtained by detecting radiation over the precordium following the intravascular injection of radioactive material. It reflects the average fraction of the end-diastolic volume ejected during systole. It is presumed that the difference between two successive measurements of the ejection fraction (i.e., the change in VEF or CVEF) reflects a change in ventricular performance. Thus, if no change in performance occurs, the CVEF is zero; if performance worsens, the CVEF will be less than zero (i.e., it will be negative).

If 17 counts of safe passage offer little reassurance, what can account for the Seattle groups' belief that the outcome of their study "underscore(s) the need for a reappraisal of the cardiovascular risks of tricyclic antidepressants. . .?"

The problem may lie in the deceptive appeal of average change scores with values close to zero. Indeed, a change score measurement close to zero conveys virtually the same information as a report of safe passage. Unfortunately, such scores may lend themselves to overinterpretation.

To illustrate the point, consider the change in baseline ventricular ejection fraction (CVEF) associated with tricyclic use. As mentioned earlier, if tricyclics have no effect on the ventricular performance, the mean value of the CVEF (VEF on drug-VEF baseline) in the population of depressed patients with heart disease will be zero. Of course, it will not be zero for every patient. In fact, for purposes of assessing safety, the variability of the CVEF is as important a measure as the mean itself. Specifically, even if the mean is zero, a substantial proportion of patients might still be at considerable risk if variability in the population is great. Thus, the assurance given by Veith and associates that their study had an 84 percent chance to detect a change of 10 percent in the mean VEF (i.e., a negative CVEF equal or greater than one-tenth of the baseline VEF) is not as comforting as it appears at first reading. This is because we are not so much interested in the mean value of the CVEF (as it is essentially zero) as we are in the relative proportion of the population that will have clinically important CVEF values (i.e., ones with larger negative values).

A more appropriate goal of a safety assessment, therefore, is to construct statistical tolerance limits for the CVEF. Because we are only interested in decrements in ventricular performance, we wish to find one-sided limits. Specifically, we wish to find a value, A, above which at least a proportion P, of the population will lie (Natrella 1963).

Tables for calculating such limits exist. Using resting CVEF data for the nine sickest drug-treated patients (mean CVEF was 0.01; sample standard deviation reported as 0.03) the following may be stated with a 90 percent confidence: assuming normality, at least 90 percent of the distribution will have a CVEF greater than a value equal to the sample mean minus the product of the tabled value of K (2.133 for a sample size of nine) and the sample standard deviation. $[\text{Lower limit of CVEF} = 0.01-(2.133 \times 0.03) = -.054]$. (*See* Table A-7 in Natrella 1963.) In other words, 10 percent of the population can reasonably be expected to have a 0.05 or greater fall in their VEF at rest when treated with tricyclics. Even this estimate, however, may be too optimistic. The tolerance limit calculations are based upon the assumption that the patient sample is a random one from the population (i.e., that it is representative) and upon the assumption that CVEF scores follow a normal distribution. Neither of these assumptions need be correct.

Assuming, however, that the tolerance limits are reasonably accurate, how clinically significant will a fall of 0.05 units in resting VEF be for 10 percent of depressed patients with serious heart disease? Obviously, there is no ready answer. It does seem reasonable, however, that a fall of this sort is more likely to be important to the patient with marginal cardiac reserves than it is to the typical patient in the Seattle study who had VEFs in the normal range.

These calculations have been presented to illustrate the limits of safe passage arguments. From the perspective of the public health, 17 patients is very few indeed. It is of interest to this author that Veith and his associates recognized the problem when they noted that their results could not provide an estimate of the risk of sudden death. They clearly recognized that failure to detect an event in a small number of subjects is not especially reassuring. However, when Veith and his colleages were able to measure a variable, they behaved as though they had additional information which permitted them to make stronger inferences about safety than they might had they interpreted their experience as 17 counts of safe passage. In this author's view, it is more appropriate (i.e., conservative) to treat the measurements of cardiovascular performance as merely "hard data" corroboration (i.e., an independent check) of each count of safe passage.

Viewed in this light, the more or less uneventful passage of 17 mildly ill cardiac patients would not justify a reappraisal of the risks of tricyclic drugs. Indeed, syncope, a major recognized risk of tricyclic treatment for the patient with cardiovascular disease, did occur. Incidentally, this clinically significant event would not have been identified by examining the mean values for increments in orthostatic hypotension observed in each drug-treated group.

Before ending the column, this author wants to emphasize that his concern is not with the work nor with the results of the investigative team that conducted this very well-designed and interesting clinical trial. We will all be well served if the work in Seattle is continued, and if other studies, of similar design, are conducted. This author's concern is with the relatively strong implication of relative safety presented by the paper, especially in its lead abstract. While the author hopes that the implication is warranted, he fears that it may not be. Until larger samples of more severely ill cardiac patients are studied, wisdom suggests that tricyclics be used with caution in patients with compromised cardiovascular function.

Brief Reports—

Supersensitivity, Drug Withdrawal, and Open Field Behavior

João Palermo-Neto, M.S., Ph.D.[1]

The open field has been used to study withdrawal from long-term drug treatment (Bernardi & Palermo-Neto 1979; Bernardi et al. 1981; Capaz et al. 1981; De Lima & Palermo-Neto 1980; Palermo-Neto & De Lima, in press). Thus, abrupt withdrawal from long-term haloperidol administration in increasing doses enhanced general activity of rats in an open field (Bernardi & Palermo-Neto 1979). Identical findings were observed after withdrawal from long-term treatment with diphenylhydantoin (De Lima & Palermo-Neto 1980), ethanol (Capaz et al. 1981), and sodium barbital (Palermo-Neto & De Lima 1982). The open field was also used to compare the effects of single and long-term haloperidol administration (Bernardi et al. 1981). The effects of withdrawal from the neuroleptics were explained by a development of supersensitivity in the central dopaminergic receptors. Indeed, a significant displacement to the left of the dose-response curve for apomorphine-induced stereotypy in rats on abrupt haloperidol withdrawal was observed (Bernardi et al. 1981). Central nervous system (CNS) supersensitivity was also used to explain withdrawal effects for the remaining drugs employed. Thus, in ethanol-withdrawn mice a positive correlation was found between locomotion plus rearing frequencies and audiogenic-induced seizure susceptibility (Capaz et al. 1981). Equal results were detected after withdrawal from long-term diphenylhydantoin (De Lima & Palermo-Neto 1981) and sodium barbital (Palermo-Neto & De Lima 1982). In these latter two studies, drug removal also made rats more sensitive to convulsions elicited by maximal transcorneal electroshock.

There is a close relation between CNS supersensitive phenomena and the "withdrawal syndrome" observed after withdrawal from long-term administration of CNS-depressant drugs (Collier 1966, 1968; Sharpless 1964, 1969, 1975). In rats, the main characteristic of this syndrome is a hyperexcitability state characterized by a greater tendency to convulsions independent of the pattern and nature of the elicitor stimuli (Essig 1967; Kalant et al. 1971). Thus, it seems that both the increase in seizure susceptibility and the increment in general activity of withdrawn rats are simply a manifestation of CNS supersensitivity induced by the long-term drug depression (Sharpless 1969). According to Sharpless (1964), this phenomena is probably a compensatory mechanism developed against the long-term depressant effect of the drug, induced perhaps to maintain homeostasis. Indeed, withdrawal signs were not detected in rats after gradual withdrawal from long-term haloperidol treatment (Bernardi & Palermo-Neto 1979). Furthermore, comparing the effects of single and long-term haloperidol administration, the author observed a correlation between the impairment of motor function induced by different doses of haloperidol, singly administered, and the increment of general activity observed after withdrawal from long-term neuroleptic administration (Bernardi et al. 1981).

It is important to emphasize concern that the author is referring to postsynaptic supersensitivity, also named "denervation" or "disuse" supersensitivity, where the major synaptic change involved is at the postsynaptic receptors (Tarsy & Baldessarini 1974). Specificly, the author believes that, in his experiments, the long-term interrup-

---

Send correspondence to Dr. Palermo-Neto at Faculdad de Medicina Veterinaria USP, Farmacologia Aplicado e Toxicologia, Av. Corifeu de Azevedo Marques, 2720, 05340 São Paulo, SP, Brazil.

tion of synaptic transmission resulted in supersensitive receptors to the endogenously released neurotransmitter or to its related agonists. This hypothesis seems true. Indeed, haloperidol blocks postsynaptic dopaminergic receptors (Ljungberg & Ungerstedt 1977) and diphenylhydantoin, ethanol, and sodium barbital interfere with synaptic transmission in presynaptic terminals blocking different processes of Ca^{++}-dependent neurotransmitter release, such as noradrenaline (Blaustein 1976; Pincus & Lee 1973; Williams et al. 1975). In this respect, catecholaminergic systems are related both to general activity (Dunstan & Jackson 1976) and to convulsion spread (Jobe et al. 1973). Further, it was shown that noradrenaline plays an important role in barbiturates withdrawal (Morgan et al. 1978; Tabakoff et al. 1977).

Thus, it seems that hyperactivity, a classic and insufficiently explored symptom of early drug withdrawal (Martin 1977), is one of the many behavioral manifestations of CNS supersensitivity. So, quantification of these behaviors in an open field displays the phenomena. Indeed, as sound or high levels of illumination inside the apparatus were not used, it is supposed that the subject will habituate to, and hence be minimally influenced by, aspects of test situations other than the specific stimulus component being used as the independent variable, in the author's studies, drug withdrawal.

Tiapride in Tardive Dyskinesia

D.J. Murphy, M.R.C. Psych.,[1] G. Hughes, M.B. B.Sc.,[1] and G.K. Shaw, F.R.C. Psych.[1]

Introduction

Tardive dyskinesia is manifested by a wide variety of involuntary movements including orolingual dyskinesia, chorea, athetosis, dystonia, tics, and facial grimacing, but excluding rhythmic tremor (APA Task Force Report, 1980). There is substantial evidence that the pathogensisi of tardive dyskinesia relates to chronic dopamine receptor blockade produced by long-term administration of antipsychotic drugs (Gardos & Cole 1980).

Drug treatment of tardive dyskinesia has been ineffective (Editorial, *Br. Med. J.* 1981). Many clinical trials demonstrate improvement in a proportion of patients but few patients in any given trial have shown more than 50 percent improvement (Gardos & Cole 1980).

Tiapride (N-diethylaminoethyl methoxy-2-methyl sulphonyl-5-benzamide hydrochoride) is closely related structurally to both metoclopramide and the antipsychotic drug sulpiride. It differs from typical neuroleptics in animals models for neuroleptic activity: it fails to induce catalepsy, displays weak sterotypy antagonism, weak ability to displace neuroleptic ligands, and inactivity in inhibiting dopamine sensitive adenylate cyclase (Jenner et al. 1978).

It inhibits perioral dyskinesias induced by the striatal injection of dopamine in animals (Costall & Naylor 1977), reduces levodopa-induced peak dose involuntary movements (Lees et al. 1979), and produced a marked improvement in buccofacial dyskinesia in the elderly (Courrier et al. 1978). In the present study the antidyskinetic potential of tiapride was examined on chronic psychiatric patients with tardive dyskinesia.

Method

Eight patients were selected from the wards of a large psychiatric hospital. They all had a casenote diagnosis of chronic schizophrenia. Their clinical features and medication history are summarized in Table 1. It was not possible to discover the length of time for which dyskinesia had been present, but it was not less than 5 years in any patient. Likewise, exact duration of neuroleptic therapy was difficult to establish but was never less than 20 years. All patients displayed involuntary movements of the orolingual or facial musculature. While the authors were inexperienced in neurological practice, efforts were made by casenote perusal and clinical evaluation to exclude patients with a neurological disorder (other than tardive dyskinesia) or those displaying stereotyped movements of schizophrenia. Baseline psychotropic medication remained unchanged for the 6-week trial period, and during the trial no patient received any other medication affecting dopaminergic or cholinergic neurotransmission. Tiapride was administered in three daily doses at 8:00 a.m., 1:00 p.m., and 6:00 p.m. Dosage is recorded in Table 2. The dose was increased after a week if response was not marked.

Movements were recorded by video-filming in a standardized manner as described by Kidger et al. (1980) at the same time of day (afternoon) each week. The scoring format for abnormal movements by Kidger et al. (1980) was used by the authors who jointly viewed the tapes. Filming was done before tiapride was introduced and thereafter at weekly intervals before dosage was

increased and at the conclusion of the trial. Parkinsonian effects were measured using the rating scale of Simpson and Angus (1970) before the start and at the conclusion of the study.

Results

The effects of treatment are summarized in Table 2. At the conclusion of week 6, when all but one patient were on 600 mg of tiapride per day, one patient was worse, three were marginally worse, one remained the same, two were marginally improved, and one was improved. Mean dyskinesia score before treatment was 4.13 ± 1.81 S.D.: at maximum dosage of tiapride was 4.25 ± 1.83 S.D. (not statistically significant). During the course of the trial, seven of the eight patients did show improvement on initial ratings but this was not maintained. One patient was noticed to have ceased a grunting sound which he was accustomed to make which initially we had not considered to be a dyskinetic phenomenon but in retrospect might have been due to diaphragmatic dyskinesia. Another patient not rated as improved was reported by nursing staff to be able to hold a cigarette in her mouth which she had not been capable of previously. In patients 2, 6, and 7, the dose of tiapride was increased to 800 mg per day for 2 days only after week 6 with marginal improvement in one patient only. The mean parkinsonism score rose from 8.75 ± 5.50 S.D. to 10.86 ± 4.74 S.D. at maximum dose of tiapride (not significant: Student's *t*-test), but this did not seem to impair everyday activities. One patient dropped out of the trial because of transfer to a hostel and in another the full dosage increase was not possible because of hypotension. No marked changes in mental state were noted in any patient.

Discussion

The results of the investigation suggest that tiapride does not have a clinically significant antidyskinetic action in patients with chronic tardive dyskinesia. The work was prompted by the theory that there are two different populations of dopamine receptors in the striatum (Jenner & Marsden 1979), those whose blockade caused neuroleptic-induced parkinsonism and those whose hypersensitivity is responsible for dyskinetic movements (Costall & Naylor 1977). The failure of tiapride to influence these receptors

Table 1

Patient Data and Baseline Medication

Patient No.	Sex	Age	Approximate Duration of Previous Neuroleptic Treatment (years)	Neuroleptics During Investigation	Anticholinergics During Investigation
1	M	56	20	Clopenthixol 800 mg I/M 2-weekly	Procyclindine 10 mg daily
2	M	53	20	Haloperidol 12 mg daily	Procyclidine 15 mg daily
3	M	66	24	None	Procyclidine 5 mg daily
4	M	64	20	Clopenthixol 100 mg I/M 3-weekly	Procyclidine 10 mg daily
5	M	61	25	Clopenthixol 200 mg I/M 3-weekly	Procyclidine 10 mg daily
6	F	65	25	None	None
7	M	65	20	Fluphenazine Decanoate 75 mg I/M 3-weekly	Procyclidine 10 mg daily
8	M	74	25	Thioridazine 225 mg daily	None

in the dose-dependent manner expected from a mechanism of postsynaptic blockade poses some questions. Was this a condition in which irreversible changes had taken place? This seems likely. Marsden et al. (1975) reported that the risk of permanent tardive dyskinesia was around 30 percent of those developing the problem and the general ineffectiveness of treatment has been alluded to previously. However, sulpiride, which is similar to tiapride, was reported to reduce tardive dyskinetic movements in a dose-dependent manner by Casey et al. (1979). Differences between Casey's group and that of the authors' study were that his subjects had a lower mean length of neuroleptic treatment, and only 5 of his 11 subjects had a diagnosis of schizophrenia.

The finding of a nonsignificant increase in parkinsonism is in accordance with Casey et al.'s results with sulpiride lending indirect support to the theory of subpopulations of striatal dopamine receptors. However, at variance with the findings are those of Lees et al. (1979) and L'Hermitte et al. (1977) who found a marked increase in parkinsonism with smaller doses of tiapride albeit in patients with idiopathic parkinson's disease. The finding that levodopa induced peak dose movements were reduced in the studies of Lees et al. (1979) and L'Hermitte et al. (1977) underlines differences in the pathophysiology of the two conditions.

Reservations about the general applicability of the findings are as follows. A small group of elderly subjects were used, most of whom remained on neuroleptic and anticholinergic medication which may have affected the action of tiapride. A rating scale was used which measured the site and duration of movements and not the intensity. Perhaps the dose was increased too rapidly. A greater response might have been obtained at higher doses than were used. The investigators feel that further preliminary studies are warranted, particularly on a less chronic population.

Table 2

Dosage, Tardive Dyskinesia, and Parkinsonism Scores

Patient No.	Dose[a] T.D. Score[b]	Before Tiapride	Duration of Treatment (Weeks)						Parkinsonism Score[c]	
			1	2	3	4	5	6	Before Tiapride	At Maximum Dose of Tiapride

[a] Total daily dose of tiapride (mgs)

[b] On scale of Kidger et al.

[c] On scale of Simpson and Angus.

Conclusion

Tiapride, a substituted benzamide derivative closely related to metoclopramide, failed to have a marked beneficial effect in seven of eight patients in a 6-week open study on patients with chronic tardive dyskinesia. Despite the use of high doses, increase in parkinsonian symptoms was not significant, lending support to the notion of separate groups of dopamine receptors. The authors' results underline the intractability and possible irreversibility of the syndrome.

Acknowledgment: Thanks are due to Drs. T. Kidger and T.R.E. Barnes for helpful advice, to Mrs. J. Johns, and to Mr. G. Samuel of Chemitechna, Ltd., who supplied medication.

Haloperidol Plasma/Red Blood Cell Ratios and Clinical Efficacy[1]

Robert Neborsky, M.D.,[2] David S. Janowsky, M.D.,[2] James Perel, Ph.D.,[3] Ethan Munson, D.O., B.A.,[2] and Dennis Depry, M.D.[2]

Introduction

Although the ability to accurately measure serum and red blood cell (RBC) levels of antipsychotic agents and their metabolites by a variety of techniques has advanced greatly during the past decade (Clark et al. 1977; Cohen & Hershel 1979; Creese & Snyder 1977; Hornbeck et al. 1979; Rubin et al. 1980), utilization of these analytic techniques to assess which dose of a given neuroleptic is indicated in a specific patient has been less useful than originally hoped for, although several studies have suggested some relationship between serum and/or RBC levels of neuroleptics and clinical efficacy (Casper et al. 1980; Davis 1980).

The present study is part of a previously reported experiment designed to evaluate the relationship of high- and relatively low-dose haloperidol administration to outcome in acutely ill psychotic inpatients (Neborsky et al. 1981). In this study, the relationship of plasma and RBC levels of haloperidol, as well as the relationship of the ratio of plasma to RBC haloperidol levels to antipsychotic efficacy, has been studied.

Method

In a study (Neborsky et al. 1981) intended to investigate the effects of rapid neuroleptization and subsequent short-term maintenance with low- and high-dose haloperidol, a total of 20 acutely psychotic male inpatients were utilized. Although originally diagnosed by Diagnostic and Statistical Manual-II (DSM-II) criteria, these subjects were later diagnosed retrospectively by DSM-III criteria. Based on the later criteria, the following was found: schizophreniform disorder, $N=11$; brief reactive psychosis or schizophreniform disorder, $N=1$; schizophrenic disorder, paranoid type, $N=1$, schizophrenia, undifferentiated type, $N=5$; major affective disorder, manic episode, $N=2$.

Of these 20 subjects, 10 were randomly assigned to a 10 mg dose haloperidol treatment group and 10 patients were assigned to a 2 mg dose haloperidol treatment group. Each patient then received a series of double-blind haloperidol administrations in a three-phase sequence. Treatment Day 1 was subdivided into two phases (Phases I and II). During Phase I, which consisted of an intramuscular rapid neuroleptization phase, patients received at least 1 and up to 5 hourly injections of haloperidol, given until tolerance for oral medication was possible. During Phase II, the oral rapid neuroleptization phase, the patients received the same 2 mg dose or 10 mg dose of oral haloperidol, respectively, as they had received in Phase I, up to a maximum of four additional doses. At 8:00 a.m. the following day, the patients were entered into Phase III, the oral maintenance phase, which lasted for 6 more days. During this phase, the patients received a total number of 2 or 10 mg doses each day. This data is equal to the total administered during Phase I plus II. However, the treating physician was permitted to blindly alter the number of dosages based on behavioral observations. Table 1 displays the mean milligrams of haloperidol administered during each of the three phases.

Table 1

Milligrams Haloperidol Administered During Three Experimental Phases Expressed as Mean ± SEM

Dosage	Phase I[a]	Phase II[b]	Total of Phase I + II	Average Daily Dose During Phase III[c]
2 mg/dose	8 ± 0.6	2 ± 0.5	10 ± 0.6	12 ± 0.7
10 mg/dose	29 ± 2.0	14 ± 4.0	45 ± 3.0	38 ± 4.0

[a] Phase I = Rapid Intramuscular Neuroleptization Phase
[b] Phase II = Rapid Oral Neuroleptization Phase
[c] Phase III = Oral Maintenance Phase

Behavioral responses to treatment were measured in part using the Brief Psychiatric Rating Scale (BPRS) of Overall and Gorham (1962). The BPRS was completed at baseline, and at the end of Phase III. Daily 9:00 a.m. bloods were drawn in heparinized tubes, centrifuged, separated into plasma and RBC fractions (which were allowed to lyze), and frozen at −40°C. Selected plasma and RBC samples were measured for haloperidol levels from the same sample by the radioimmunoassay technique of Perel et al. (1981) and Shostak and Perel (1976). Although the majority of the blood samples analyzed for this report were drawn on the last day of Phase III, certain samples analyzed were drawn on other days due to sample loss (mean day ± SEM = 6.85 ± .27).

Results

As described previously, there was no difference in overall clinical outcome between the high- and low-dose haloperidol treatment groups (Neborsky et al. 1981). Regardless of dosage, early clinical improvement during the first day of treatment (Phases I and II) predicted eventual improvement at the end of Phase III (Neborsky et al. 1982). Despite no overall dose-related differences in improvement between treatment groups in clincial outcome, there were substantial differences in improvement within groups (Neborsky et al. 1982). Some patients' symptoms nearly returned to a remitted baseline state, while others were completely refractory to treatment.

In examining the relationship between measured haloperidol levels, plasma and RBC haloperidol levels were found to differ significantly between the high- and low-dose groups. The high-dose group's plasma levels averaged 33.9 ± 5.0 ng/ml (mean ± SEM) and the high-dose RBC levels averaged 40.8 ± 5.7 ng/ml, whereas the low-dose groups averaged 8.2 ± 0.8 ng/ml and 9.3 ± 1.0 ng/ml, respectively. The average oral dose administered to each patient correlated significantly with the average plasma ($r = .639$, $p < .001$), and RBC concentrations ($r = .759$, $p < .001$), and a strong correlation between plasma and RBC haloperidol concentrations ($r = .975$, $p < .001$) was also found.

As shown in Table 2, there was no significant correlation of either plasma or RBC haloperidol levels with either baseline, or absolute or percent

Table 2

Correlations of Haloperidol Plasma Levels, Red Blood Cell Levels, and Plasma/Red Blood Cell Ratios with Clinical Improvement After 7 Days of Treatment in 20 Acutely Psychotic Psychiatric Inpatients

	Baseline BPRS Scores	Absolute Improvement in BPRS	Percent Improvement in BPRS
Plasma Concentration of Haloperidol	.061	.109	.101
Red Blood Cell Concentration	.085	−.023	−.064
Plasma/Red Blood Cell Ratio	−.126	.496[a]	.640[c]
Red Blood Cell/Plasma Ratio	.141	−.560[b]	−.715[c]

[a] = $p < .05$
[b] = $p < .01$
[c] = $p < .001$

improvement in psychopathology, as measured by the BPRS change scores between the baseline an the end of the maintenance phase. In contrast, the ratio of either plasma to RBC or RBC to plasma haloperidol concentrations demonstrated a strong and statistically significant correlation with both the absolute BPRS change scores and the percent change in the BPRS from the beginning to the end of the study, but did not correlate at all with baseline BPRS scores. The ratios showed a range from 0.907 to 1.599 for the RBC/plasma ratio, and from 0.625 to 1.103 for the plasma/RBC ratio. The range of the plasma/RBC haloperidol ratios and their relationship to improvement on the BPRS are displayed in the Figure.

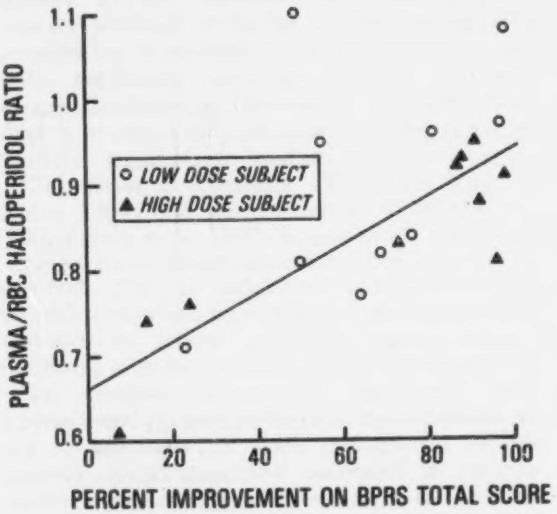

FIGURE. The relationship of plasma/RBC haloperidol ratios to percent improvement in the BPRS following 7 days of treatment in 20 acutely psychotic inpatients.

Discussion

The results are unsupportive, at least in acutely ill psychotic psychiatric inpatients, of the assertion that haloperidol dose and plasma and RBC haloperidol levels as such are useful indicators of clinical efficacy, at least when clinically accepted doses of haloperidol are utilized. This observation is different from that of some others who reported dose-effect relationship between haloperidol levels and efficacy (Calil et al. 1979; Ericksen et al. 1978; Forsman et al; 1977; Magliozzi et al. 1981; Tune et al. 1980). The reason for this difference is difficult to accurately appraise, because of study design variations and patient sampling differences between studies, but it is clear that the study was of very short duration, lasting only 7 days. If the study had been carried out for a longer time, or with a larger number of patients, a more classic dose response curve might have become apparent. Another difficulty with the study is that it was not a fixed-dose study, so that with each dosage group, respectively, an artificial triphasic relationship could have been produced (Cohen & Baldessarini 1981; Neborsky et al. 1981). A further difficulty in the design is the fact that the patients may not have reached steady-state blood levels, so that the oral dose to blood level correlations may be misleading (Forsman & Ohman 1975, 1976). A final weakness of this study is the fact that the patient group, although all psychotic, was diagnostically mixed, and was generally acute, rather than chronic schizophrenics. It is conceivable that a more homogenous group of subjects, or subjects with a poorer prognosis, would not have shown the significant correlations between plasma/RBC haloperidol ratios and clinical outcome.

Nevertheless, the observation that plasma/RBC haloperidol ratios may reflect clinical efficacy, regardless of dose, may have potential theoretical and practical implications. If plasma/RBC haloperidol ratios, analyzed early in treatment of a patient are found to eventually predict efficacy data, a valuable clinical tool may be developed. Furthermore, it is possible that *in vitro* techniques for examining plasma/RBC neuroleptic level ratios, prior to initiating neuroleptic treatment, may offer a clinical tool for prediction of response to neuroleptic therapy beyond the trial and error methods currently in use.

Cholinomimetic-Induced Co-Release of Prolactin and Beta-Endorphin in Man[1]

S. Craig Risch, M.D.,[2,4] David S. Janowsky, M.D.,[2,4] Larry J. Siever, M.D.,[3] Lewis L. Judd, M.D.,[2] Jeffrey L. Rausch, M.D.,[2] Leighton Y. Huey, M.D.,[2,4] Kimberlee A. Beckman,[2] Robert M. Cohen, M.D.,[3] and Dennis L. Murphy, M.D.[3]

The endorphins have been mechanistically implicated in the hypothalamic modulation of anterior pituitary prolactin release, presumably by affecting hypothalamic neurotransmitter activity regulating anterior pituitary prolactin release mechanisms (Meites et al. 1979; Van Vugt & Meites 1980). In animal studies (Gold et al. 1979; Grandison & Guidotti 1977; Rivier et al. 1977b; Shaar & Clemens 1980; Van Vugt & Meites 1980) and human studies (Catlin et al. 1980; Extein et al. 1980; Schulz et al. 1980), the intravenous or intraventricular administration of beta-endorphin or exogenous opioids, such as morphine or methadone, produce dose-dependent increases in plasma prolactin concentrations. Similarly, in animal studies, administration of the opiate receptor antagonist, naloxone, may depress basal plasma prolactin concentrations, as well as attenuate or block endogenous or exogenous opioid-associated increases in plasma prolactin concentrations (Grandison & Guidotti 1977; Guidotti & Grandison 1978; Meites et al. 1979; Rivier et al. 1977b; Shaar & Clemens 1980; Van Vugt & Meites 1980).

These studies suggest that the endogenous opioid peptides may be important in the normal physiological regulation of anterior pituitary prolactin release.

It is believed that endogenous opioid peptide effects on anterior pituitary prolactin release are probably not due as such to direct effects on hypothalamic hormones regulating pituitary function (Meites et al. 1979), nor are they believed to be due to a direct opioid effect on the pituitary, since beta-endorphin does not stimulate prolactin release from hemipituitaries (Shaar et al. 1977) or from cultured pituitary cells (Rivier et al. 1977a, 1977b). Rather, it is currently hypothesized that endogenous opioid peptides modulate anterior pituitary prolactin release via actions on hypothalamic neurotransmitters such as dopamine and serotonin, which in turn regulate the release of hypothalamic hormones into the hypothalamic pituitary portal vasculature. Specifically, beta-endorphin has been demonstrated to reduce medial basal hypothalamic concentrations of dopamine, both *in vivo* (Deyo et al. 1979; Van Loon et al. 1980a; 1980b; Van Vugt et al. 1979) and *in vitro* (Enjalbert et al. 1979; Wilkes & Yen 1980). In addition, other studies have suggested that endorphins and enkephalins may increase brain serotonin turnover (Algeri et al. 1978; Van Loon & De Souza 1978), and may thereby modulate anterior pituitary prolactin release (Cusan et al. 1977; Spampinato et al. 1979).

In addition, considerable evidence, albeit conflicting, suggests a relationship between central acetylcholine and plasma prolactin activity. In a series of animal experiments by Grandison et al. (1974) and Grandison & Meites (1976), centrally or systemically administered cholinomimetics reduced basal prolactin levels, reduced the daily nocturnal surge of prolactin, reduced prolactin rises in female rats or estrogen-treated male rats

at proestrus, and reduced prolactin rises subsequent to stress, ether, or 5-hydroxytryptamine (5-HTP) administration. Subramanian and Gala (1976) also report that both nicotinic and muscarinic cholinergic agonists prevent the afternoon circadian surge in ovariectomized, estrogen-treated rats. However, in the same study (Subramanian & Gala 1976), these investigators noted that high doses of atropine also attenuated this afternoon surge of prolactin in ovariectomized, estrogen-treated rats. McLean and Nikitovich-Winer (1975) also reported that high-dose atropine in animal studies inhibited the nocturnal rise in prolactin secretion, an effect which could be blocked by pretreatment with physostigmine. Libertun and McCann (1973) similarly reported that intraventricular or subcutaneous atropine could inhibit prolactin release in rats. In contrast, Lawson and Gala (1975), using cholinergic receptor agonists and antagonist pharmacological probes in animal studies, were unable to demonstrate any effect of these agents on basal prolactin levels.

In spite of the varying effects of cholinomimetic drugs on plasma prolactin levels in animals, the intravenous administration of centrally active cholinomimetics, such as physostigmine, an acetylcholinesterase inhibitor with both nicotinic and muscarinic cholinomimetic properties, or arecoline, a relatively selective muscarinic agonist, consistently produces significant increases in plasma prolactin, as well as beta-endorphin immunoreactivity in human subjects (Risch et al. 1980, 1981).

From these human results, these investigators have hypothesized that the cholinomimetic-induced increases in prolactin concentrations, observed in these investigators' previous studies, might reflect cholinergic activation of hypothalamic beta-endorphin release mechanisms as described above.

These investigators now describe three separate studies in three groups of human volunteer subjects in which centrally active cholinomimetic agents and placebo controls are used to define correlations between cholinomimetic-stimulated increases in hypothalamic-pituitary release of beta-endorphin and increases in plasma prolactin concentrations.

Method

In three separate experiments, the relationship of physostigmine as well as arecoline-induced increases in plasma prolactin and beta-endorphin immunoreactivity was studied. In the first experiment, nine normal volunteers (5 male, 4 female, ages 18-29) at the National Institute of Mental Health (NIMH) received physostigmine salicylate 33 μg/kg and saline placebo. In the second experiment, eleven normal volunteers (all male, ages 21-30) at the University of California at San Diego received physostigmine salicylate 22 μg/kg and saline placebo. In the third experiment, six normal volunteers (2 male, 4 female, ages 19-28) at the NIMH received arecoline hydrobromide (3 mg) and saline placebo.

All three studies were conducted under a Food and Drug Administration-approved investigational new drug (IND) and with local Human Subjects Committee approval, and all subjects gave written informed consent. Studies were conducted between the hours of 8:00 a.m. and 11:00 a.m. under randomized, double-blind conditions in which subjects, after pretreatment with methscopolamine 1.0 mg intramuscular (i.m.) or glycopyrrolate 0.2 mg intravenously (i.v.) received either placebo (normal saline) or active drug (physostigmine 22 μg/kg or physostigmine 33 μg/kg or arecoline 3.0 mg), as described above, on 1 day and received the other condition at least 2 days later, given over a 10-minute period. In each study, after an adaptational period of 30 minutes subsequent to the insertion of an indwelling heparin lock catheter, subjects had blood samples for neuroendocrine measurements drawn at 30, 15, and 0 minutes prior to active drug or placebo infusion, and at 10, 20, 35, and 50 minutes subsequent to each 10-minute infusion.

Plasma concentrations of beta-endorphin and prolactin were determined by radioimmunoassay as previously described (Kalin et al. 1981; Risch et al. 1980, 1981). The antibody for beta-endorphin demonstrates a 50 percent cross-reactivity, with beta-lipotropin, but less than 0.01 percent with alpha-endorphin, alpha-MSH, and less than 0.004 percent with leucine enkephalin and methionine enkephalin. Within-assay variability for beta-endorphin is approximately 56 percent and sensitivity is 25-50 pg/ml. The antibody for prolactin has cross-reactivities of hTSH <0.3 percent, hLH <0.1 percent, hFSH <1 percent, and hGH <0.03 percent. Within assay, variability for prolactin is approximately 5 percent and sensitivity is 5 ng/ml. In each of the three studies, all samples for plasma beta-endorphin or prolactin determinations were assayed within the same assay.

Significance of changes in plasma beta-endorphin and prolactin immunoreactivities were determined by repeated measures analysis of variance. Linear regression analyses were performed to determine the relationships and significance of cholinomimetic-induced changes in plasma prolactin and beta-endorphin immunoreactivities within individual subjects.

Results

In Experiments 1 and 2, highly significant increases in plasma beta-endorphin and prolactin immunoreactivity occurred after physostigmine infusion, but not after placebo, similar to those previously reported by these investigators (Risch et al. 1980, 1981). Changes in plasma concentrations of beta-endorphin and prolactin immunoreactivities subsequent to physostigmine were highly correlated, as described in Figures 1 and 2.

Similarly, in Experiment 3, significant increases in plasma beta-endorphin and prolactin immunoreactivities also occurred after arecoline, but not after saline placebo. As with the physostigmine infusions, changes in plasma concentrations of beta-endorphin and prolactin immunoreactivities subsequent to arecoline infusion were highly correlated, as illustrated in Figure 3.

Discussion

In three separate studies, changes in plasma concentrations of beta-endorphin were highly correlated with changes in plasma concentrations of prolactin. In addition, as depicted in Figures 1, 2, and 3, there were no increases in plasma prolactin concentrations in the absence of increases in plasma beta-endorphin concentrations. Although high correlations between exogenously administered opioids and subsequent prolactin release have been previously reported, this is the first report of such an association between endogenously stimulated opioids and changes in plasma prolactin concentrations.

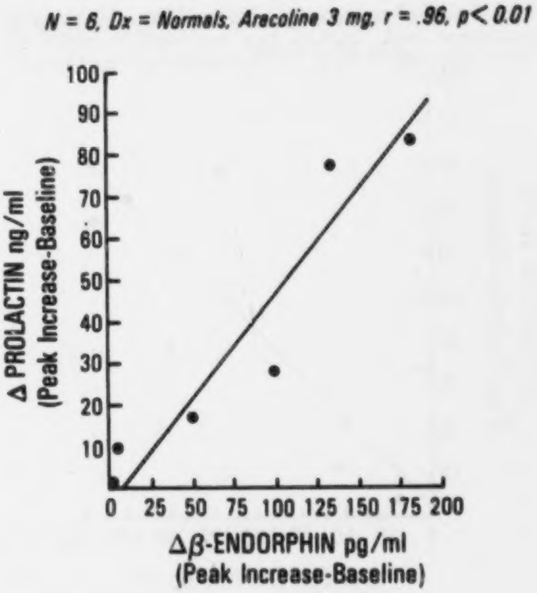

FIGURE 1

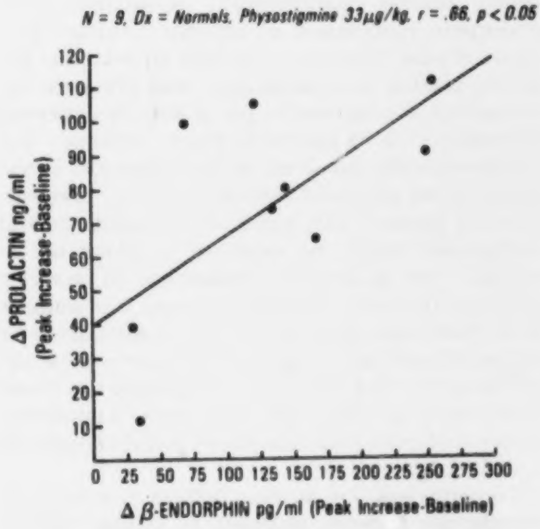

FIGURE 2

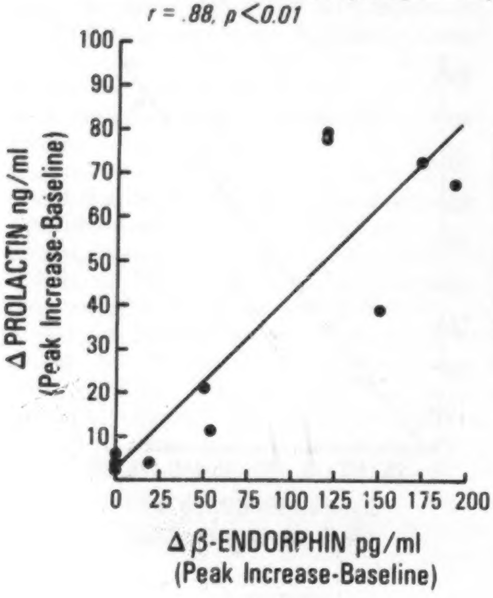

FIGURE 3

As reviewed above, these high correlations may reflect central cholinergically stimulated beta-endorphin modulation of anterior pituitary prolactin release. However, the high correlations between plasma beta-endorphin and prolactin increases do not necessarily prove that the observed increases in beta-endorphin release are mechanistically involved in the prolactin elevations. If the proposed model is correct, pretreatment of subjects with naloxone, a specific opioid antagonist, might be expected to block or attenuate the endorphin stimulation of anterior pituitary prolactin release. However, the authors have been reluctant to use the combination of naloxone and physostigmine because a pilot experiment in their laboratory suggested increased cholinergic toxicity, although three subsequent larger studies in their laboratory failed to replicate this finding.

Nevertheless, the authors believe that the high correlations between increases in plasma concentrations of beta-endorphin and prolactin observed in their studies provide a useful heuristic model for understanding the effects of centrally active cholinergic agents on anterior pituitary prolactin regulation. Furthermore, if the proposed model is correct, these findings may provide an interesting example of peptidergic modulation of primary neurochemical mechanisms involved in hypothalamic-pituitary prolactin regulation.

Review

Hormonal and Neurotransmitter Hypotheses of Premenstrual Tension[1]

ffrey L. Rausch, M.D.,[2] David S. Janowsky, M.D.,[2] S. Craig Risch, M.D.,[2] Lewis L. Judd, M.D.,[2] and Leighton Y. Huey, M.D.[2]

Introduction

The incidence of premenstrual-menstrual psychologic symptoms (premenstrual tension) has been estimated as between 25 and 100 percent of all women (Janowsky et al. 1971), with severity ranging from mild irritability to frank psychotic episodes (Endo et al. 1978; Smith et al. 1976). Symptoms are usually confined to the 5 days prior to menstruation, and abate with the onset of menses or shortly thereafter (Smith 1971). However, increases in negative affect have been found to occur as early as 11 days prior to menstruation, and to continue well into the menstrual phase (Janowsky et al. 1973), although these symptoms are to be distinguished from dysmenorrhea, a syndrome of menstrual pain etiologically associated with prostaglandin levels (Chan & Dawood 1980; Pickels 1979). A variety of hypotheses have been employed to explain the etiology of premenstrual tension (PMT) syndrome. Speculations have ranged from the psychosocial to the biochemical, but to date no single hypothesis has proven altogether satisfactory. This article reviews several of the major biological hypotheses concerning the etiology of premenstrual tension.

The Ovarian Hormone Hypothesis

In 1931, Frank first described the premenstrual tension syndrome and postulated its hormonal pathogenesis, a hypothesis now widely accepted, and deriving considerable support from animal as well as human studies. The ovarian hormones, progesterone and estrogen, are the two hormones which have been most widely studied with respect to premenstrual tension. Various theories have been proposed as to how alterations in these hormones may be etiologic.

Low progesterone levels have been considered etiologic of premenstrual tension. Mundy et al. (1977) studied 16 women, half of whom suffered from premenstrual tension. At 5 to 8 days prior to menstruation, the mean plasma progesterone for the premenstrual tension groups was 31 ± 10 nanomoles per liter as compared with the 45 ± 14 nanomoles per liter for the control group. These findings are comparable with those of Bäckström and Carstensen (1974), who found that in women with predominately psychological premenstrual symptoms, progesterone levels were reduced and estrogen levels increased, as compared with normal women during the week prior to menstruation. Smith (1976) reported small but significant differences in progesterone levels in sufferers of premenstrual depression, with the symptomatic group showing slightly lower progesterone levels, as compared with those of normal women during the week preceding menstruation. O'Brien et al. (1979), however, reported significantly higher levels of progesterone 10 days prior to menstruation in symptomatic women, as compared with controls although, at 4 days prior to menstruation in that study, the symptomatic group's mean progesterone level was nonsignificantly lower than the mean for the control group.

[2] Departments of Psychiatry, University of California, San Diego and San Diego Veterans Administration Medical Center, La Jolla, CA 92093.

Premenstrual-menstrual emotional symptoms may be related to falling levels of progesterone. Dysphoric emotional symptoms often begin in the luteal phase but intensify as progesterone drops from its highest levels during the luteal peak to its relatively low premenstrual level. Also, induction of depressive symptoms have been reported following withdrawal of exogenous progesterone treatment (Hamburg 1966). Dysphoria occurs in the third trimester of pregnancy, when progesterone is elevated, and increases postpartum as progesterone levels fall (Helmer & Judson 1967; Treadway et al. 1969).

It has also been suggested that premenstrual-menstrual psychologic symptoms may be related to high estrogen levels per se. As with progesterone, an increased occurrence of psychologic symptoms occurs during the luteal phase of the cycle, when estrogen levels are high. Morton (1950) reported production of a premenstrual tension-like syndrome after intramuscular injection of estrogen. However, against this hypothesis, psychologic symptoms do not consistently increase at mid-cycle, when estrogen is most elevated, nor is there evidence of increased premenstrual symptomatology in women with endogenously prolonged or increased estrogen levels, such as occurs in metropathia hemorrhagia (Taylor 1977).

As with progesterone, estrogen withdrawal has been postulated as etiologic of premenstrual tension (Steiner & Carroll 1977) with increases in emotionality occurring in the premenstrual phase correlating with falling estrogen levels (Baird & Guevara 1969). However, the premenstrual fall in serum estrogen levels may not reflect central nervous system estrogen activity, since estrogen is selectively bound and concentrated in the limbic system and hypothalamus (Anderson & Greenward 1969).

It may be that absolute or falling levels of estrogen and/or progesterone are less important in the etiology of premenstrual tension than is the ratio of estrogen to progesterone. Greene and Dalton (1953) have specifically hypothesized a high estrogen/progesterone ratio as etiologic of premenstrual tension. They supported this hypothesis by noting that intramuscular progesterone alleviates the premenstrual syndrome (Dalton 1964; Rees 1953), a finding later challenged in a well-controlled study (Smith 1976).

As further support for an estrogen/progesterone ration hypothesis Bäckström and Carstensen (1974) noted that women with anxiety as the main premenstrual symptom had significantly higher estrogen levels premenstrually, as compared to a group of healthy women. In a later publication by Bäckström and Mattsson (1975), in 15 women with premenstrual tension, a positive correlation was found between the estrogen/progesterone ratio and anxiety.

Studies of the mood effects of oral contraceptives tend to associate irritability and anxiety with a high estrogen/progesterone ratio and depressive symptoms with a low estrogen/progesterone ratio (Culberg 1972). Indeed, these two hormones often have opposite central nervous system (CNS) effects with estrogen increasing running and mating behavior (Colvin & Sawyer 1969), increasing dorsal hippocampal excitability (Timiras 1971), and lowering seizure threshold (Wooley & Timiras 1962), and progesterone counteracting these effects, at least to some extent (Selye 1942, 1969).

In summary, the ovarian hormone hypothesis holds that premenstrual symptomatology is etiologically related to the ratios of progesterone and estrogen in the late luteal phase, or directly related to absolute or falling levels of progesterone or estrogen.

Several considerations make it difficult to completely implicate estrogen and progesterone in the ovarian-linked emotional disorders. Greene and Dalton (1953) found 17 percent of their 84 premenstrual tension sufferers attributing the onset of cyclic menstrual symptoms to the menopause—a time when estrogen and progesterone are relatively low. Also, any estrogen/progesterone ratio hypothesis must account for the relative absence of symptomatology present during the pre-ovulatory period, when serum estrogen levels are markedly higher than progesterone.

Mineralocorticoid Hypothesis

A major and enduring endocrine hypothesis as to the etiology of premenstrual tension implicates the mineralocorticoids. From studies of normal women, there is some evidence that fluctuations of aldosterone may parallel the emotional fluctuations of the menstrual cycle. Aldosterone levels increase during the mid and late luteal phases, often to about twice that occurring during the follicular phase (Katz & Romth 1972; Reich 1962; Schwartz & Abraham 1975; Sundsfjord & Aakvaag 1972;), and at least one investigator has demonstrated premenstrual aldosterone peaks (Reich 1962).

The stimulus for increased aldosterone in the late luteal phase is not completely understood, but progesterone and the ovarian hormones have been implicated. Progesterone has been found to antagonize aldosterone and to cause a sodium diuresis, with a secondary increase in plasma renin activity and aldosterone secretion rates (Crane & Harris 1978). Sundsfjord and Aakvaag (1972), for example, found the pattern of increase and decrease in the plasma levels of aldosterone and plasma renin activity to be similar to those of plasma progesterone, suggesting that these fluctuations are causally related.

Aldosterone secretion may be altered in women suffering from premenstrual tension. Two early studies reported markedly increased premenstrual aldosterone excretion in symptomatic women (Janowsky et al. 1977; Perrini & Piliego 1959). However, more recent studies have failed to support these findings, in that Munday et al. (1977) found that the levels of plasma aldosterone in eight premenstrual tension patients were not consistently different from those of eight controls, despite a small surge of aldosterone in the late luteal phase. O'Brien et al. (1979), in a larger series of 28 women, found that the aldosterone level of symptomatic women on Day 24 was nonsignificantly lower than that of the control group's.

In a study indirectly measuring mineralocorticoid activity, Janowsky et al. (1973) evaluated changes in mood, weight, and urinary potassium/sodium (K^+/Na^+) ratio over a total of 15 menstrual cycles in 11 women in order to investigate whether these changes correlated in the same patients. The urinary K^+/Na^+ ratio was measured since there is evidence that, when dietary factors are controlled, this variable may in part reflect aldosterone and other mineralocorticoid effects. The data indicated that increases in negative affect, weight, and K^+/Na^+ ratio follow similar patterns in normal women when studied longitudinally. Thus, a statistically significant increase in urinary K^+/Na^+ ratio and negative affect occurred in the premenstrual phase of the cycle. The changes in the K^+/Na^+ ratio noted in this study strikingly paralleled the aldosterone excretion curve noted by Reich (1962).

Similarly, in a study of salivary samples from 30 menstruating females, DeMarchi and Tong (1972) found ovulatory and premenstrual increases in the K^+/Na^+ ratio. They noted that changes in salivary sodium and potassium composition have been observed in depressive illness, and that increased intraocular pressure has been found in women suffering from marked premenstrual tension. Finally, in support of a mineralocorticoid hypothesis of premenstrual tension, the aldosterone antagonist spironolactone has been reported to be more effective than placebo in decreasing symptoms of premenstrual tension (O'Brien et al. 1979).

In spite of the above information, some data do not support an aldosterone hypothesis of premenstrual tension. For example, as mentioned above, there is little evidence that the aldosterone activity in women with premenstrual tension is elevated. Also, other diseases such as Conn's Syndrome, associated with increased aldosterone levels, are not necessarily associated with emotional upsets.

It may thus be reasonable to hypothesize that a substance which fluctuates in parallel with aldosterone may cause the cyclic behavioral changes. Angiotensin may be a reasonable candidate for this substance, since angiotensin is an endogenous compound which probably stimulates aldosterone secretion, being activated itself in turn by renin. Angiotensin is elevated during the luteal phase of the menstrual cycle (Janowsky et al. 1971). Increases in renin activity are also found during the second half of the luteal phase (Kaulhausen et al. 1973).

Angiotensin exerts effects on animal behavior, central neurotransmitters, and autonomic functioning (Janowsky et al. 1971). It causes increased drinking behavior when given by vertegral artery infusion or intraventricularly (Fitzsimons & Simons 1969). This appears to be a cholinergic effect which can be antagonized by atropine (Janowsky et al. 1977). Angiotensin counteracts the anesthetic effects of amobarbital (Paliac & Khairallah 1967), and decreases exploratory activity in mice when given intraventricularly (Capek et al. 1969). It disrupts learned passive avoidance responses in rats, possibly from an effect on memory (Morgan & Routtenberg 1977). Furthermore, a central hypertensive effect has also been reported which appears to have cholinergic and adrenergic components (Severs et al. 1967, 1970). Immunohistochemical studies have revealed nerve fibers containing angiotensin in several different parts of the brain (Fuxe et al. 1976; Printz & Lewicki 1977), and a brain enzyme with a renin-like activity has been demonstrated (Genten & Speck 1978). The latter enzyme may be brain renin.

Prolactin Hypotheses

Like estrogen and progesterone, the pituitary hormone prolactin has been proposed as causative of the premenstrual tension syndrome (Andersen et al. 1977; Graham et al. 1978; Halbreich et al. 1976). It appears likely that prolactin levels fluctuate through the menstrual cycle, with peaks occurring at ovulation and later in the mid and late luteal phases (Tamura & Igarashi 1973). However, in some women, there appears to be little change throughout the cycle (McNeilly et al. 1973). Increased levels of prolactin have been reported in premenstrual tension patients as compared with normal controls (Halbreich et al. 1976).

Several pilot studies have suggested that bromocriptine, a dopamine agonist which decreases prolactin, may ameliorate premenstrual tension syndrome as well as premenstrual weight gain and breast enlargement (Graham et al. 1978). However, at least one well-controlled study has shown bromocriptine only equal to placebo in its efficacy in treating premenstrual tension, and others have shown no efficacy (Andersen et al. 1977; Graham et al. 1978). Furthermore, at least one study (Tamura & Igarashi 1973) suggests that prolactin does not increase in the luteal phases of anovulatory women, and Adamopoulos et al. (1972) have noted that premenstrual tension continues to occur during anovulatory cycles.

Monoamine Neurotransmitter Hypothesis

The monoamine neurotransmitters serotonin, norepinephrine, and dopamine have been widely implicated in psychiatric disorders (Barchas et al. 1978). Evidence is also available which implicates these monoamines in the pathophysiology of premenstrual tension.

Animal studies indicate that ovarian hormones and monoamines show overlapping behavioral effects. Like certain antidepressants, estrogen induces running behavior in rats (Colvin & Sawyer 1969) and, like reserpine, progesterone induces sedation in rats and other mammals (Selye 1969).

Brain monoamines and sex steroids show overlapping effects in the regulation of sexual behavior in rats. Reserpine and tetrabenazine, both monoamine depletors, may be substituted for progesterone in activating sexual behavior in estrogen-primed castrated female rats. In contrast, tricyclic antidepressant drugs and monoamine oxidase inhibitors (MAOIs) decrease sexual activation in estrogen/progesterone-primed castrated female rats, especially when brain serotonin is selectively increased (Meyerson & Sawyer 1968). Furthermore, selective depletion of rat brain serotonin induces sexual excitation, especially when brain catecholamines such as dopamine and norepinephrine are simultaneously elevated (Tagliamonte et al. 1969).

Ovarian hormones and monoamines also exhibit overlapping functions in regulating ovulation. Elevation of brain serotonin blocks superovulation in immature rats (Krodon 1969), and decreased norepinephrine levels inhibit physiological estrus as determined by vaginal smears (Airaksinen & McIsaac 1968). Norepinephrine administration into the third ventricle in large doses induces ovulation. Reserpine administration inhibits ovulation in the rat, and this effect is antagonized by the administration of MAOIs or dopamine (Sawyer 1952). Reserpine induces pseudopregnancy in rats when given systematically and following local hypothalamic administration, and this effect is also prevented by treatment with MAOI (Meyerson & Sawyer 1968; Sawyer 1952).

Dopamine appears to exhibit a very important role in the regulation of gonadotropin secretion. Small doses of dopamine, incubated *in vitro* in the presence of pituitary and hypothalamic tissue, induce the release of luteinizing hormone (LH) and follicle-stimulating hormone (FSH) (Kamberi 1970; Meyerson & Sawyer 1968). Kamberi (1970) and Schneider and McCann (1969) have recently found that administration of small doses of dopamine or relatively high doses of norepinephrine or epinephrine significantly increase blood LH levels, while serotonin causes an opposite effect (Tagliamonte et al. 1969).

Evidence is available to indicate that ovarian hormones exert an influence on MAO activity. Pharmacologic doses of estradiol are associated with decreased tissue MAO activity in rats (Collins et al. 1970; Wurtman & Axelrod 1963). Progesterone appears to increase tissue MAO activity in rats (Collins et al. 1970), and increase plasma MAO activity in amenorrheic females (Klaiber et al. 1971). Increased endometrial monoamine oxidase occurs in the late luteal phase of the menstrual cycle and in direct proportion to the progestin content of oral contraceptives (Grant & Pryse-Davies 1968). Conversely, Belmaker et al. (1974) have noted a decrease in platelet monoamine oxidase premenstrually, and these findings have been replicated by Wirz-Justice et al. (1975).

Changes in brain monoamine levels have been found to cyclically occur throughout the rat estrus cycle. Greengrass and Tounge (1971) reported that the concentration of all three monoamines decreased in the rat during estrus, a time when ovulation is being stimulated by luteinizing hormone. During metaestrus, under the influence of luteal progesterone, the monoamine neurotransmitters begin to rise toward their maximum, achieved at dioestrus when estrogen and progesterone are low.

Thus, there is evidence that alterations in monoamines may be linked to ovarian and adrenal hormone fluctuations, as well as to behavioral changes. On this basis, a catecholamine (norepinephrine/dopamine) hypothesis, and a serotonin hypothesis of premenstrual tension have evolved.

The effects of angiotensin, estrogen, and progesterone on catecholamine neurotransmitter activity have been demonstrated in a number of *in vitro* studies using neurophysiological preparations. Angiotensin can inhibit the uptake of tritiated norepinephrine by brainstem slices, perfused rat brain ventricles (Paliac & Khairallah 1967), and synaptosomes (Janowsky et al. 1971). Further, endogenous rat brain norepinephrine is lowered by intraventricular angiotensin administration (Capek et al. 1969). Estrogen itself decreases the amount of labeled pre-equilibrated tritiated norepinephrine released by electrically stimulated rat brain slices by more than 25 percent (Vogel et al. 1970).

Janowsky and Davis (1970) also reported that progesterone and estradiol block the uptake of labeled norepinephrine by synaptosomes, and that the passive efflux of pre-equilibrated norepinephrine from synaptosomes, which is slightly slowed by estradiol, is increased by progesterone. Estradiol and progesterone inhibited the uptake of tritiated dopamine and norepinephrine by synaptosomes. Progesterone (1×10^{-4}M) increased the rate of passive efflux of labeled dopamine and norepinephrine from synaptosomes, whereas estradiol (1×10^{-6}M) did not affect dopamine efflux.

In the intact female rat, exogenous estrogen has been shown to decrease hypothalamic norepinephrine. Increased norepinephrine and decreased dopamine turnover rates have been shown in the rat after castration, these effects being reversible with large doses of estradiol and progesterone. Increased dopamine turnover has been shown in the tuberoinfundibular region after estradiol (Fuxe et al. 1970). In the striaturm, chronic estradiol administration increased the density of rat dopamine receptors, and increased behavioral sensitivity to amphetamine and apomorphine stereotypy, one of many effects estrogen can have on neurotransmitter receptors (*see* McEwen et al. 1981).

Norepinephrine and dopamine are metabolized enzymatically, in part, by catechol-o-methyltransferase (COMT), and this enzyme's activity has been inhibited *in vitro* by estrogen, progesterone, and deoxycorticosterone (Kalsner 1969). In the rat midbrain, COMT has been found to decrease during estrus (Salseduc et al. 1966).

In humans, several studies have investigated various peripheral measures of catecholamine metabolism during the menstrual cycle. Wiener and Elmadjian (1962), and Patkai et al. (1974) reported increases in urinary norepinephrine excretion during the premenstruum. A later study also measured urinary epinephrine excretion and found small nonsignificant decreases during the 5 days prior to menstruation. A more recent study (DeLeon-Jones et al. 1978) measured the urinary metabolite of central norepinephrine, 3-methoxy-4-hydroxyphenylglycol (MHPG), daily in four healthy women. A statistically significant increase in MHPG was found during the late luteal phase, followed by a rapid decline 2 days prior to menstruation, with a subsequent elevation during the menses. This premenstrual drop in MHPG excretion is interesting in view of previous findings of decreased MHPG in some individuals with depressive illness (Beckman & Goodwin 1975).

During the premenstrual-menstrual phase of the cycle, sensitivity to tyramine increased, this probably being either a measure of increased noradrenergic receptor sensitivity or increased presynaptic neuronal norepinephrine activity (Chose & Turner 1977). In view of the above noted premenstrual decreases in urinary MHPG, it may be that sensitivity to tyramine is reflective of increased receptor sensitivity, complimenting decreased norepinephrine turnover and activity.

There are several lines of evidence, in addition to that described above, that would support an indoleamine role in premenstrual tension. Rats treated with a series of injections of progesterone showed increased brain serotonin uptake (Hackman et al. 1973) and turnover (Ladisich 1977) in several areas of the brain. After withdrawal of the progesterone injections, there was a decrease in brain serotonin uptake found 24 hours after withdrawal of the last progesterone injection (Hackman et al. 1973).

The uptake of serotonin into platelets has been found to be decreased in patients with depressive illness (Rausch et al. 1982), and decreases in platelet serotonin uptake have been found to occur in the premenstrual phase of the cycle (Rausch, unpublished; Taylor et al. 1981; Wirz-Justice & Chappius-Arntt 1976). The amino acid precursor of serotonin, tryptophan, has shown menstrual variations in the plasma, with increases seen premenstrually (Wirz-Justice et al. 1975).

The urinary metabolite of serotonin, 5-hydroxyindoleacetic acid (5-HIAA), has been measured across the menstrual period in normal women, and 5-HIAA excretion has been found to be higher during the secretory phase as compared to the proliferative phase, with the final descent occurring during the premenstrual phase (Lerdo de Tejada et al. 1978). This data could be consistent with the notion that luteal progesterone secretion increases serotonin turnover, with subsequent premenstrual progesterone withdrawal resulting in lowered serotonin turnover.

The serotonin hypothesis may bear some relevance to the mineralocorticoid hypothesis discussed above, since administration of the serotonin precursors tryptophan and 5-hydroxytryptophan have been found to stimulate renin in dogs, and stress can lead to increases in both plasma renin and brain serotonin (Check 1980). Furthermore, corticosterone itself can increase or decrease serotonergic function, depending on the dose (Aubert et al. 1971).

Acetylcholine Hypothesis

Some evidence exists that cholinergic mechanisms may be etiologic in the premenstrual-menstrual emotional upsets. Angiotensin increases brain acetylcholine content in rat and mouse and causes an increase in the output of acetylcholine from the parietal cortex of cats. It causes an increase in the secretion of antidiuretic hormone, which appears to be cholinergically mediated and itself is water retaining. Consistent with these observations, it has been noted that the uterine hyperemia which precedes menstruation is due to increased acetylcholine activity, and neostigmine, a cholinesterase inhibitor, can induce menstruation in nonpregnant women who have delayed menstruation, presumably by increasing uterine acetylcholine activity. Furthermore, a variety of ovarian hormones and other steroids can increase acetylcholine activity in physiologic preparations and can increase sensitivity to acetylcholine in muscle preparations.

Menstrually related remission of symptoms has been demonstrated in patients suffering from myasthenia gravis, and are asssociated with cyclic variations of red cell acetylcholinesterase activity, suggesting a hormonal influence on acetylcholinesterase activity (Vijayan et al. 1977). Physostigmine, a centrally acting cholinomimetic drug, alleviates manic symptoms and causes withdrawal, lethergy, dysphoria, psychomotor retardation and, in some cases, depression in normals, remitted patients, schizophrenics, and manics (Janowsky et al. 1972). Possibly, then, the premenstrual-menstrual emotional upsets in part represent a relative predominance of central cholinergic activity, caused by angiotensin or a variety of endogenous steroid compounds. Finally, there is some evidence that a proprietary combination drug containing an ergot, a barbiturate, and an anticholinergic agent can alleviate premenstrual tension better than placebo can (Robinson et al. 1977). If this finding is valid, and if the effects are due to the anticholinergic agent, this would support a role for acetylcholine in the ovarian-linked emotional disorders.

Summary

In the above paragraphs, the authors have reviewed several of the major hypotheses proposed to explain the etiology of premenstrual tension. Although there is evidence that premenstrual tension is linked to changes in hormones and/or neurotransmitters, the need for further research to confirm or refute the various hypotheses exists, and represents a challenge for the future.

Psychopharmacology and the Anxiety Disorders Workshop

This special section of the *Psychopharmacology Bulletin* is devoted to proceedings at a workshop entitled, "Psychopharmacology and the Anxiety Disorders," held in Washington, D.C. on February 8-9, 1982. This was a relatively small meeting with 17 panelists and 15 guest scientists or staff from the National Institute of Mental Health. The workshop provided a forum for investigators to present their latest findings in this rapidly developing field and to try to resolve points of disagreement. There is now no question that psychoactive drugs, principally the antidepressants, are effective treatments for panic attacks and for obsessive-compulsive disorders. Evidence is also accumulating that the antidepressants are effective treatments for generalized anxiety disorders.

A major theme of the workshop was the possible mechanism(s) of action of the antidepressants as treatments for these disorders.

The articles that follow are expanded versions of papers presented at this workshop.

Diagnostic Classification of Anxiety and Phobic Disorders

David V. Sheehan, M.B., B.Ch., B.A.O.[1] and Kathy H. Sheehan, M.S.[2]

In order to understand and investigate anxiety disorders and correctly assign patients to treatment, it is helpful to have a diagnostic classification system. Such a diagnostic classification is like a map to a traveller: without it he may get quite lost, with it he is guided to any destination and his journey is eased considerably.

The multiaxial diagnostic system, recently introduced by Diagnostic and Statistical Manual-III (DSM-III), eliminates much of the confusion of past diagnostic systems. In this system each patient receives a diagnosis at five levels—one diagnosis for each axis.

Axis 1 - A diagnosis of the clinical psychiatric syndrome based on the clinical description of symptoms and signs.

Axis 2 - A personality disorder diagnosis based on the individual's character structure and mode of interaction with his environment.

Axis 3 - A diagnosis of medical (nonpsychiatric) disorder.

Axis 4 - Severity of psychosocial stressors.

Axis 5 - Highest levels of adaptive functioning in the past year.

This paper will focus on an Axis 1 diagnostic classification for anxiety disorders, i.e., the diagnosis of clinical psychiatric syndrome based on a description of the symptoms and signs. This is the preeminant, central axis to which the others are secondary.

Goals of Classification

The immediate goal of a classification system is to organize phenomena in a systematic way into categories in which members of each category have common characteristics, e.g., symptoms, signs, demography, pathophysiology, etiology, natural history, family history, and treatment

[2] Massachusetts General Hospital, Institute of Health Professions, Boston, MA 02116.

response. This is not intended as an obsessive academic exercise. The long-range purpose of having a good classification guide is to:

1) help predict what will happen to a patient who falls into one class based on the past experience with other patients in that class;

2) help control the symptoms by being able to predict and manipulate what will happen in several contingencies; and

3) clarify the relationship between the phenomena, e.g., the symptoms observed.

Classification is useful insofar as it helps to predict, clarify, and control what is going to happen.

Criteria for Classification

A good classification system satisfies the following criteria:

1) The classes are inherently mutually exclusive, i.e., each class is clearly distinct from the other classes; no class overlaps with another class;

2) the classes are internally homogenous, i.e., each class is internally consistent and homogenous within itself;

3) the classification system is comprehensive, i.e., it has a category for all cases;

4) it helps to clarify the relationship between the phenomena in question;

5) it permits better prediction and control; and

6) it is simple, economical, and clear.

The authors' comments will focus on the special importance of having classes that are inherently mutually exclusive and the proscription of significant category overlap. For if that first criterion is not satisfied, the classification system breaks down and the other criteria are meaningless.

Methods of Classification

There are many methods of setting up a classification system. The theological approach is to consult a consortium of experts and distill their collective wisdom. A more scientific approach involves two exploratory stages and a final testing or confirmatory stage. The first exploratory stage involves a cluster analysis of presenting symptoms in a large population to separate the symptoms into distinct groups. The second stage involves a discriminant analysis on these clusters to determine the symptoms (or criteria) with the highest discriminatory power between the clusters. These discriminating variables now become the diagnostic criteria for each class in the classification. The final confirmatory stage calls for a test of these new discriminating variables on a fresh patient population for their ability to a) comprehensively assign all cases into b) mutually exclusive groups.

The authors took the position that existing classification schemes for the anxiety disorders had completed the exploratory stages in arriving at the diagnostic criteria for each category. What remained was to test the existing classification systems to see how well their diagnostic criteria could comprehensively assign patients into mutually exclusive groups.

Table 1

Diagnostic Labels Synonymous with Endogenous Anxiety

Anxiety Hysteria Hysteria (early descriptions) Globus Hystericus	**Atypical Depression** Grand Hysterie Hysterical Neurosis Vertigo Hysterique
Anxiety Neurosis Anxiety Syndrome Pseudo Neurosis Borderline States (Klein, 1964) Locomotor Anxiety	Anxiety States (*Lancet*,1952) Severe Mixed Neurosis Pseudoneurotic Schizophrenia Non-Specific Insecurity Fears Street Fear
Phobic Anxiety State	**Agoraphobia**
Phobic Anxiety Depersonalization Syndrome Separation Anxiety Effort Syndrome	Phobophobia Severe School Phobia Irritable Heart Syndrome
Da Costa's Syndrome Cardiac Neurosis Hyperdynamic B Adrenergic Circulatory State Nervous Tachycardia	Neurocirculatory Asthenia Soldier's Heart Antonomic Epilepsy Vasomotor Neurosis Vasoregulatory Asthenia Hypogylcemic Syndrome
Hyperventilation Syndrome Panic Disorder Autonomic Epilepsy	**Hypochondriacal Neurosis** Depersonalization Neurosis Depressive Anxiety States

Deficits in Existing Classifications of Anxiety Disorders

In one study, a list of diagnostic labels was collected from the past records of approximately 60 patients (Sheehan et al. 1980). All patients described the same set of symptoms. All had spontaneous panic attacks and all were polyphobic. The diagnostic labels had been given for the same set of symptoms, over a period of 20 years. Table 1 illustrates the range of diagnoses given to these patients. The diagnostic confusion reflected in this table suggested two possible explanations. One explanation reflected negatively on the diagnostic abilities of the evaluating psychiatrists. The second explanation was that the classification system for anxiety disorders was itself the source of the confusion. Obviously the second explanation was preferable, since it was more flattering to Boston psychiatrists. The list in Table 1 included many labels in DSM-II (1950) as well as others that had found historical favor with various groups.

In an effort to test the mutual exclusivity of existing diagnostic categories, symptom checklist, scale, and interview data were analyzed on 100 consecutive patients who sought treatment for anxiety attacks and multiple phobias at a Massachusetts General Hospital Psychiatry Clinic (Sheehan & Sheehan, in press-a,b,c). Because of the multitude of labels, it was necessary to choose for the testing phase only those for which there were precisely defined, replicable, diagnostic criteria and for which there was some consensual validation. The criteria of Feighner et al. (1972) and the Research and Diagnostic Criteria (RDC) (Spitzer et al. 1975) and DSM-III criteria (1980) satisfied this demand. The diagnostic criteria of Feighner et al. (1972) had three diagnostic labels which were relevant to this patient population: 1) hysteria 2) anxiety neurosis, and 3) phobic neurosis. Others including Perley and Guze (1962) had also proposed earlier variations of diagnostic criteria for hysteria. Table 2 shows the percentage of patients who satisfied the Feighner et al. diagnostic criteria for each diagnostic category. The majority of patients simultaneously fulfilled all of the criteria for a diagnosis of hysteria, and anxiety neurosis and phobic neurosis. As shown in Tables 3 and 4, they also satisfied the criteria for several RDC and

Depersonalization Disorder	47
Hypochondriasis-Physical Health	68
Dysthymic Disorder	92

DSM-III categories simultaneously (DSM-III, 1980; Spitzer et al. 1975). This same sample of patients was found elsewhere to have a homogenous age of onset distribution, and a significant majority subsequently had satisfactory therapeutic responses to tricyclics and monoamine oxidase inhibitors (1980).

As indicated in Table 4, these figures were obtained when "exclusionary criteria" in the DSM-III were eliminated from the testing set of criteria. An exclusionary criterion is one that states that if a patient is given diagnosis X, he cannot also get diagnosis Y. An example from DSM-III (1980) is the last (exlusionary) criterion for panic disorder which states that such patients cannot have agoraphobia. It is by such charades that the pretense of mutually exclusive categories is maintained. However, there is no evidence in nature that having panic disorder confers an immunity against the development of agoraphobia. Indeed, quite the opposite seems to be the case. From this test on a fresh population it appears that these classification systems fail to satisfy the first criterion of a good classification—that of having categories that are mutually exclusive. Clearly there is considerable category overlap in these systems. The fable of the 10 blind men and the elephant may be relevant here. Each blind man holds a different part of the elephant and, in describing the part he holds, claims that it is the elephant. What is called for is a comprehensive overview and integration. If a patient seeks a physician's help stating he is anxious or describes some anxiety symptoms, there are 21 to 25 diagnostic categories in the DSM-III to which he might reasonably be assigned (*see* Table 5) (Sheehan & Sheehan, in press-a). Depending on the interest, or orientation of the diagnostician, any one or more of the patient's symptoms in the large cluster he suffers might be chosen and a diagnosis given around that cluster. Those with a medical model would favor panic disorder, while those with a behavioral orientation might select agoraphobia and social phobia.

21 Overanxious Disorder	+	+	−	−	−	−	−	−	−	+	+	+	−	+	+	+	−	+	−	−	21

As if it were not confusing enough to remember those 21 categories, the DSM-III recognizes that some of these categories could coexist. It therefore allows for the possible coexistence of some categories (1980). Table 6 outlines the relevant diagnostic categories that are permitted to coexist (+) and those that are not (−). This figure reveals that there are approximately 138 possible combinations of such diagnoses allowed by the DSM-III (1980). When a patient presents with a complaint of anxiety, the clinician has 138 combinations of diagnoses to consider. There may be more diagnostic combinations permitted than the patient has symptoms, a lucid example of misplaced precision. This makes useful comparison of studies from one center to the next difficult.

Case Illustration: Limits of a Cross-Sectional Perspective

Consider the following case of a patient admitted to the inpatient service at Massachusetts General Hospital, a patient whose entire cluster of symptoms responded well to phenelzine and behavior therapy (*see* Table 7) (Periy & Guze 1962;Spitzer et al. 1975).

Two years before admission the patient had attacks of unreality. At that point she fulfilled the criteria for a DSM-III diagnosis of depersonalization disorder (1980). One year prior to admission she became hypochondriacal about a few fleeting symptoms and sought much medical attention. At that point she fulfilled the DSM-III criteria for a diagnosis of hypochondriasis (1980). Six months prior to admission, the hyperactive episodes of autonomic manifestations of anxiety permitted the DSM-III label generalized anxiety disorder (1980). Three months prior to admission she choked on food while anxious and subsequently feared eating solid foods. This was sufficient to justify the label simple phobia, since this was now

Table 7

DSM-III Case Illustration

Time Before Treatment	DSM-III Diagnosis at Time
2 years	Depersonalization Disorder
1 year	Hypochondriasis
6 months	Generalized Anxiety Disorder
3 months	Simple Phobia
1 month	Social Phobia
6 days	Agoraphobia Without Panic Attacks
Admission	Conversion Disorder
1 week post-admission	Panic Disorder
2 weeks post-admission	Agoraphobia With Panic Attacks

her central concern. Her fears generalized so that before long she feared eating with her friends, going to restaurants, socializing at parties, being the focus of attention, eating with her family and, finally, even being seen eating by anyone. She preferred to eat alone. She had a social phobia. One week prior to admission she had a devastating panic attack while out driving and subsequently feared leaving her home. This was agoraphobia without panic attacks (she had not had three panic attacks over a 3-week period). With considerable effort, her family desensitized her to go out again. Their concern led to her being evaluated and admitted. On admission, the consultant described her central concern as preoccupation with choking sensations and a lump in her throat. This he diagnosed a conversion disorder (DSM-III) or what in the past would have been labeled globus hystericus. One week after admission she had a series of spontaneous panic attacks and now satisfied panic disorder criteria. Two weeks after admission, she was fearful of going anywhere. She could not leave the ward and even feared leaving the security of her room. She had agoraphobia with panic attacks (DSM-III) (1980).

Are we now to presume that this young lady had nine different diseases in the space of 2 years? If she had been seen cross sectionally at time period 3, would the authors have concluded she had generalized anxiety disorder and recommended a benzodiazepine? Or at time period 4, would a simple phobia have been described and behavior therapy and *in vivo* exposure been suggested? Or at time period 7, with a diagnosis of conversion disorder, might psychotherapy or hypnosis have been considered? At time period 8, the authors could comfortably recommend imipramine.

Clearly, a cross-sectional view can mislead. A more logical approach would be to view the case longitudinally as a process passing through several stages.

Stages of the Disorder: A Longitudinal Perspective

The majority of patients with this disorder may pass through the following seven stages in the natural progression of their illness (Sheehan & Sheehan, in press-c).

Stage 1 Subpanic Symptoms
Stage 2 Panic
Stage 3 Hypochondriasis
Stage 4 Single Phobia
Stage 5 Social Phobias
Stage 6 Agoraphobic Polyphobic Behavior
Stage 7 Depression

First, they usually suffer sudden episodes of isolated symptoms short of panic with little or no immediate stress, such as tachycardia, lightheadedness, or shortness of breath. These episodes may be followed by full-blown panic attacks which are more intense, and complete clusterings of several of these symptoms in the same time frame. Because there is frequently no apparent immediate stimulus for their physiology racing out of control, patients become hypochondriacal and repetitiously seek medical assistance. Over time, spontaneous panic attacks occur in increasingly varied situations. These spontaneous panic attacks can classically condition these situations to later elicit phobic anticipatory anxiety to these situations (induce single phobias). Over time, as the patients accumulated more phobias, they become more socially phobic and finally polyphobic and agoraphobic. Finally, as they become progressively restricted, and attempts at treatment fail, and they feel depressed and discouraged by their restrictions. All of these stages might be collapsed telescope fashion, into a short period of time. On the other hand, the progression may be protracted over many years or arrested at any one stage. It is the relentless onslaught of frequent, intense spontaneous panic attacks that dictates the rapidity and completeness of progression through the stages. (Sheehan & Sheehan, in press-a,c). This longitudinal perspective helps resolve the diagnostic confusion of many labels generated by the cross-sectional perspective (Sheehan & Sheehan, in press-a).

Toward a More Heuristic Classification

As a step towards a simpler, more practical classification system to guide research efforts and clinical management, a decision tree to another classification system is offered in Table 8 (Sheehan et al. 1981, Sheehan & Sheehan, in press-b,c). This classification proposes two kinds of anxiety disorders. The presence or absence of spontaneous anxiety or symptom attacks that occur with little or no stress is the key differentiating point that triages a patient to one or other category (Sheehan et al. 1981; Sheehan & Sheehan, in press-b,c). The exogenous anxiety category is an anxiety that normal people can relate to. It occurs when someone is suitably traumatized or under stress or has a specific monophobia with anxiety that is exclusively bound to only one stimulus. The endogenous anxiety is associated with multiple symptoms, e.g., panic attacks, and eventually complicated by the acquisition of multiple phobias (Sheehan et al. 1981; Sheehan & Sheehan, in press-b,c). The exogenous category is stress-related, while the endogenous appears to be a genetically inherited metabolic disease (Sheehan et al. 1980, 1981). Both exogenous and endogenous anxiety can be subdivided into subtypes along acute to chronic and mild to severe/complicated continua (*see* Table 8) (Sheehan & Sheehan, in press-b,c). In the endogenous anxiety class, phobias usually occur. The presence of phobias in such patients appears to be a function of the intensity and frequency of the spontaneous panic attacks. The identity of the phobia appears to be a function of the situation in which intense panic attacks occurred. Subsequently, the phobias are reinforced both from within the individual by the spontaneous panic attacks and are triggered by a classically conditioned response to the environmental stimulus to which they have been conditioned (Sheehan & Sheehan, in press-c). Over time, the phobias are reinforced both from within and from outside the individual (Sheehan & Sheehan, in press-c).

Is there evidence to support such a clustering? There are data to suggest that the age of onset distribution, sex ratio, and treatment response are different in the two kinds of anxiety (Sheehan et al. 1980, 1981). In endogenous anxiety, the age of onset distribution is uniformly unimodal, consistent with a biological illness model. In exogenous anxiety, the age of onset is evenly distributed through all ages, consistent with a stress induction or conditioning model (Sheehan et al. 1981). Table 9 lists the diagnostic criteria for each major category, followed by the other suggested points of differentiation.

As long as classification systems depend exclusively on symptom clustering, it is unlikely that consensus will be reached among investigators. Consensus will probably await the development of laboratory techniques such as psychophysiological measures, blood or other laboratory tests, genetic marking, and pharmacological dissection. These will undoubtedly lend validity to some existing classification system and add refinements that will be clinically meaningful. In the meantime, the above analysis and classification system may offer investigators and clinicians a clearer starting point and easier guide to correct diagnosis and treatment.

Table 9

Diagnostic Criteria

Endogenous Anxiety	Exogenous Anxiety
1. Spontaneous, autonomous, clonic, phasic, (subjectively reported) episodes of the following symptoms: (1-2 for a minor attack, 3 or more together for a major attack): (a) Skipping or racing of heart (b) Dizzy spells or faintness (c) Air hunger, difficulty getting breath, or hyperventilation (d) Smothering or choking sensation (e) Tingling or numbness (paresthesias) in hands, arms, feet, or face (f) Nausea or upset stomach or vomiting (g) sudden unexpected panic or anxiety feelings occurring with little or no provocation (h) Hot flushes or cold chills (i) Jelly legs or imbalance (j) Shaking or trembling (k) Derealization or depersonalization (l) Chest pain, pressure or discomfort (m) Hypochondriasis (n) Feeling will lose control, scream or "go insane" or die (o) Spontaneous clonic alteration in sensory perception e.g. increased or decreased clonic sensitivity to light, sound, touch, temperature taste, proprioception, muscle power (p) Diarrhea attacks (q) Sweating episodes	1. No spontaneous panic or anxiety attacks or history of the same
2. Such symptom attacks have persistently recured for at least one month. Within a 3 month period, at least 3 discrete major attacks must occur for a diagnosis of major endogenous anxiety, or at least 3 discrete minor attacks for a diagnosis of minor endogenous anxiety. Symptoms must occur in the absence of any psychotic disorder or medical illness that could explain the symptoms.	2. Tension and symptoms of anxiety occur *only* in response to immediate, clearcut, =identifiable environmental stimuli. Onset of each attack not very sudden or unexpected but related to immediacy of triggering stimulus. In the case of conditioned changes in motor, sensory symptoms or special senses the symptom may occur alone without any overt anxiety.
3. Phobic symptoms particularly fear of a spontaneous panic attack (phobophobia) and fear of crowded places. Phobias start only after onset of first spontaneous panic attack. Phobia may fluctuate in intensity over time.	3. Phobia restricted to one specific focus. Monophobic rather than polyphobic. Phobia rarely fluctuates in intensity over time.
4. Depression, neurasthenia (excessive tiredness and feeling everything is an effort), obsessive compulsive symptoms present to some degree in over 2/3 of cases.	4. Depression, neurasthenia, obsessive-compulsive symptoms-and other gross psychophathology absent.
5. Anxiety profile of spontaneous panic attack as in Figure 1 (although Figure 2 type may also occur)	5. Profile of anxiety attack as in Figure 2
6. Spontaneous fluctuations on GSR	6. No spontaneous fluctuations on GSR
7. Slow habituation rate on GSR	7. Normal or rapid habituation on GSR
8. Elevated resting pulse rate	8. Resting pulse within normal range

Table 9 (Continued)

9. Brisk reflexes	9. Reflexes not hypertonic
10. Family history of anxiety attacks and phobic symptoms especially among female relatives	10. Positive family history rare
11. Age of onset usually 12-40 years	11. May occur at any age
12. 80 percent of cases occur in women	12. ?Equal sex distribution
13. More likely to have visited medical doctor and emergency ward several times for treatment of symptoms. Spontaneous anxiety must occur: 1. In absence of medical illness that could cause such symptoms 2. In absence of life-threatening situations	13. Rarely seeks medical or emergency ward treatment
14. More likely to have seen several psychiatrists in treatment over many years.	14.
15. More likely to have had a hospital admission and surgical treatment for symptoms.	15.
16. Response to MAO inhibitors and imipramine good	16. Response to drugs poor.
17. Response to behavior therapy alone poor.	17. Response to behavior therapy good
18. Autonomy of clonic phasic course e.g. does not immediately improve when environmental circumstances seem favorable.	18. More clearly responsive to psychosocial stimulus
19. Anxiety attacks precipitated by sodium lactate I.V. and by marijuana administration	19. Anxiety attacks not precipitated by either lactate or marijuana

New Antianxiety Agents

Jonathan O. Cole, M.D.[1]

As stated by Greenblatt in his paper in this publication (p. 58), there is no real reason to expect that newer benzodiazepines (e.g., prazepam, halazepam) which are converted by the body into desmethyldiazepam will have antianxiety effects different from chlorazepate. Indeed, it is very hard to find differences even between less closely related benzodiazepines (BDPs) with quite different pharmacokinetics (e.g., diazepam and lorazepam). The possibility that one of the new triazolo-benzodiazepines, alprazolam, may have atypical efficacy in the treatment of panic states, as described by Sheehan (personal communication) and in depression (Feighner, in press) does suggest that further molecular changes in the BDP molecule *might* yield different or superior clinical actions.

There has been continuing interest in the use of older, marketed non-BDP drugs in anxiety. Propranolol has been suggested as especially useful in somatic or cardiac anxiety symptoms or in anxiety-related tremor. The available evidence only suggests a weak antianxiety effect of propranolol in anxious outpatients (Altesman et al. 1980). There are, of course, a growing number of newer beta-blocking drugs which might be studied for antianxiety effects, but it is hard to tell whether such studies would be productive.

The recently completed National Institute of Mental Health collaborative study comparing imipramine, chlordiazepoxide, and placebo in nondepressed anxious outpatients (Kahn et al. 1981) is showing that imipramine has unsuspected efficacy in anxiety. This effect comes on slowly, and some patients drop out because of imipramine's side effects. Other antidepressants deserve similar study. At least one new potential antidepressant, synaptamine, a mianserin analog, is being studied both in anxious and in depressed patients.

Another approach to the uncovering of new antianxiety drugs is the study in man of non-BDP substances which bind to BDP receptors. At least one such compound, CL 230, 482, a pyrazolo pyrimidine, is currently in early clinical trial in the United States. It is too early to tell whether this rational approach will yield an unfortunately rational result—the drugs may turn out to be exactly like existing BDPs in everything except chemical structure, reminding one of the "nonbarbiturate" hypnotics developed 30 years ago; these turned out to be at least as bad as the barbiturates in all respects, although chemically different.

The author is acquainted with one new antianxiety drug, buspirone, developed by Mead Johnson. It has been studied in anxious patients (Goldberg & Finnerty 1979; Rickels, in press) and has been shown to be as effective as diazepam. Recently it has been studied against diazepam and placebo in a large multiclinic study in anxious outpatients. These studies indicate that the drug is equipotent to diazepam with less sedation, good effect on anxiety, and some superiority over diazepam in reducing irritability and hostility as measured by the Symptom Check List (Newton, in press). Studies on the drug's abuse liability done in recreational sedative abusers at McLean Hospital are showing that at a higher dose (40 mg), buspirone is dysphoric although sedating and therefore unlikely to be abused (Cole et al. 1982).

All this is of some extra interest because buspirone has no effect on BDP receptors and has an odd mixture of dopamine agonist and antagonist properties. It reverses neuroleptic-induced catalepsy in rodents both at low and at very high doses. It blocks the conditioned avoidance response without affecting escape, but also relieves conflict-induced behavioral suppression at doses similar to those at which diazepam has this "classic" antianxiety drug effect. Buspirone has neither neuroleptic nor BDP effects on social behavior in the rat, resembling low-dose piribedil, a presumed presynaptic dopamine agonist. It is much weaker at potentiating barbiturates than is diazepam. It is not anticonvulsant. In the cat, buspirone has effects on the quantitative electroencephalogram which resemble apomorphine. However, buspirone is an antiemetic. It does not produce physical dependence in rats (Riblet, in press).

---

[1] Psychopharmacology Services, McLean Hospital, Belmont, MA 02178.

Buspirone thus may be the first member of a quite different class of antianxiety drugs without the mild but bothersome abuse problems found with BDPs.

Hopefully, we are entering a new phase in the antianxiety area. For many years, the main and almost the only available drug group for treating depression was the tricyclic group, parallelling the BDPs in anxiety. Now a host of chemically and pharmacologically diverse antidepressants (e.g., trazodone, mianserin, zimelidine, nomifensine, buproprion) are available or in late clinical trial. Maybe buspirone will turn out to be effective and safe; maybe the new non-BDP drugs binding to BDP receptors will be usefully different; maybe some beta-blocker will be a first-class anxiolytic; maybe (quite likely) there are other new antianxiety drugs waiting in the wings unknown to us. One cannot be sure, but things seem to be looking up.

Animal Models of Anxiety: Implications for Research in Humans

Thomas W. Uhde, M.D.,[1] Jean-Philippe Boulenger, M.D.,[1] Larry J. Siever, M.D.,[2] Robert L. DuPont, M.D.,[3] and Robert M. Post, M.D.[1]

In humans, behavioral and biological alterations may be associated with the subjective experience of anxiety (Krause 1961). However, no behavioral, biochemical, or neurophysiological correlates have been found to be specifically and consistently associated with the experience of anxiety. It is only by verbal report, therefore, that an observer can reliably detect the presence or absence of anxiety. In contrast, investigators using animal models must rely exclusively upon the behavioral and neurophysiological changes that develop in response to specific stimuli. Although it is impossible to develop specific criteria for anxiety in animals, there may be some useful parallels among the biological systems of nonhuman and human organisms.

Most animal models relevant to the topic of anxiety have been developed as systems for identifying drugs that may have anxiolytic properties in humans, rather than as attempts to induce a disorder in animals equivalent to the experience of anxiety in humans (Iversen 1979).

Models of Behavioral Inhibition

All of these models are based on the common principle that a number of different stimuli will induce a behavioral inhibition in animals (perhaps a consequence of fear) which can be antagonized by the administration of anxiolytic drugs (Gray 1981). The main purpose of these models is to differentiate the specific anxiolytic effect of the drug from sedation which would reinforce the behavioral inhibition (Simon & Soubrie 1979). The most commonly used of these models is the conflict test developed by Geller and Seifter (1960) in which the animals are conditioned to inhibit active food-seeking behavior in response to a signal of punishment. The barbiturates, meprobamate, and the benzodiazepines reinstate the suppressed behavior despite the occurrence of punishments, at doses which correlate well with their reported anxiolytic effects in humans (for review, *see* Sepinwall & Cook 1978). This so-called "anti-punishment" effect of anxiolytic drugs has been documented in several animal species (Dantzer 1977) as well as in humans (Carlton et al. 1981). However, no convincing results have been obtained on the conflict test with other substances such as morphine, ethanol, or beta-blockers, also known to have antianxiety effects (Sepinwall & Cook 1978).

These situations of conditioned fear, where a predictable and objectively unpleasant effect is expected, are different from those involving uncertainty, an emotion which may more closely approximate the human experience of generalized anxiety (File 1980). Uncertainty, triggered by a novel environment and/or different levels of illumination, has also been used in animal models to induce a decrease of exploratory behavior (Boissier et al. 1976; Crawley 1981) or social interactions (File 1980). Benzodiazepines also reverse the behavioral inhibition associated with these paradigms. It is interesting in this regard that agoraphobia may develop in some patients as a result of spontaneous panic attacks (Klein 1964, 1967) and that many patients restrict their life-

style and avoid social interactions, presumably in response to the unpredictability of these attacks.

Separation Behavior in the Monkey

The use of the monkey may help to avoid some of the drawbacks encountered with the use of rodents, especially problems related to the interpretation of fear-associated behaviors. In rhesus monkeys, a forcible separation from an attachment object during rearing has been shown to induce a propensity in later life to exhibit behavior patterns typically associated with fear reactions but occurring in the absence of any obvious and immediate fear stimulus (Suomi 1981). The manner and the relative frequency with which these animals display symptoms characteristic of fear (perhaps similar to some types of anxiety experienced in humans) depends on the amount and type of stress encountered and on constitutional factors such as autonomic responsivity to auditory stimuli (Suomi 1981). The effects of antianxiety agents (benzodiazepines) on this model have not been investigated, although preliminary results suggest that imipramine not only inhibits the depressive symptomatology induced by separation, but decreases the amount of protest behavior displayed by young monkeys during separation (Suomi 1981). These findings are interesting in relation to the beneficial effects of imipramine described in some categories of pathological anxiety in humans, e.g., panic attacks and agoraphobia (Klein 1964; Uhlenhuth 1981).

It is also noteworthy that separation in primates has been used as a model of depression, suggesting some further parallelism with the human situation where both anxiety and depressive syndromes often occur simultaneously and respond to common treatments such as the tricyclic and monoamine oxidase inhibitor (MAOI) antidepressants.

Lack of response to escapable shock following exposure to inescapable shock or "learned helplessness" has likewise been conceptualized as a model of both depression and "anxiety-related" behavior; learned helplessness also responds to treatment with antidepressants (Anisman 1982; Maier & Seligman 1976; Seligman 1975). An interesting aspect of this model is its sensitization and conditioning characteristics; behavioral impairment increases with increasing numbers of exposures. This and related sensitization models may be particularly useful in the conceptualization of mechanisms underlying the at times progressive development of psychopathology observed in some clinical anxiety syndromes (Post & Ballenger 1981). Panic attacks and generalized anxiety may, in some instances, increase in frequency and severity leading to progressive incapacity of the patient. Models which take into account the longitudinal course of symptoms may be of particular value in conceptualizing mechanisms and therapeutic interactions which may differ greatly depending on when in the acute or chronic time course they are considered.

Kindling is another model which helps to focus on the longitudinal and progressive development of symptoms in addition to possible limbic system substrates, and the relationship of antianxiety and anticonvulsant effects of drugs such as the barbiturates and benzodiazepines (Post & Ballenger 1981; Post & Kopanda 1976). In kindling, animals show increasing behavioral electrophysiological and convulsive responses to repeated, intermittent stimulation. Limbic areas such as the amygdala and hippocampus are most susceptible to kindling (Goddard et al. 1969). Anxiety is one of the common effects reported in patients following spontaneous or induced seizures of the limbic system. It is of interest that selected drugs are both anxiolytic and potent anticonvulsants.

The Locus Coeruleus as a Model of Anxiety

Recent advances in research techniques provide unique opportunities for studying the behavioral consequences of both "turning-on" and "turning-off" specific brain systems. Although several neurotransmitters have been implicated in the biological functions of fear and arousal, the noradrenergic system may be especially interesting in this regard (Boulenger & Uhde 1982; Redmond & Huang 1979; Uhde et al. in press). In studes in the rhesus monkey, Redmond (1977) and Redmond and Huang (1979) investigated the behavioral effects of both increasing and decreasing the activity of the locus coeruleus, the major brain noradrenergic nucleus located in the pons with projections to the cerebral cortex, cerebellum, limbic system, and spinal cord. Redmond (1977) and Redmond and Huang (1979) demonstrated that electrical and pharmacological activation of the locus coeruleus produced behaviors (e.g., eye scanning, head and body turning, scratching, biting fingers or nails, hand wringing, pulling hair) similar to those observed in monkeys exposed to natural threats in the wild. In contrast, electrical lesions and pharmacological inhibition of the locus coeruleus decreased these same fear-associated behaviors. For example, the microiontophoretic application of the alpha-2 adrenergic antagonists, yohimbine and piperoxane, simultaneously increased locus coeruleus firing and fear behaviors. Conversely, drugs which decrease locus coeruleus firing such as morphine, desmethylimipramine, MAOIs, and clonidine reduced fear-associated behaviors. These findings in the monkey may have interesting parallels in man. That is, drugs which increase locus coeruleus activity (piperoxane, yohimbine, methylxanthine) (Redmond 1977; Redmond & Huang 1979) or decrease it (morphine, desmethylimipramine, MAOIs, ethanol, diazepam) (Aghajanian 1978; Grant et al. 1980; Korf et al. 1974; Nyback et al. 1975; Redmond & Huang 1979; Strahlendorf & Strahlendorf 1981a,b) have been reported in humans to have anxiogenic and anxiolytic properties, respectively. Furthermore, propranolol, a beta-blocker with an anxiolytic profile in some humans also attenuates the postsynaptic effects of the norepinephrine released as a result of locus coeruleus activity (Redmond 1979). The relationship of locus coeruleus function to fear behaviors in the monkey, the potent inhibition of locus coeruleus activity by clonidine, and the fact that clonidine decreases both central and peripheral norepinephrine activity in man (Hanson & Hökfelt 1981; Leckman et al. 1980; Uhde, Siever, Post, and Jimerson, unpublished manuscript) led to the hypothesis that clonidine might have anxiolytic properties.

The Effects of Clonidine on Anxiety

Svensson et al. (1978) first reported in an open and uncontrolled study that clonidine had antianxiety properties in a group of patients with unspecified anxiety disorders. Uhde and coworkers (1980a) also found that clonidine dramatically decreased self- and nurse-rated items of anxiety in a group of nine opioid-addicted patients abruptly withdrawn from methadone. This antianxiety effect in addicted patients is noteworthy, since many symptoms of opiate withdrawal are similar to symptoms of severe anxiety. The authors' preliminary unpublished data also indicate that many panic-anxious patients obtain high ratings on the Addiction Research Center Inventory Subscale for Weak Opiate Withdrawal (ARCI) (Haertzen 1966), supporting the hypothesis that some aspects of opiate abstinence and panic anxiety may involve alterations of a common neurophysiological system.

As part of an ongoing anxiety research program at the National Institute of Mental Health (NIMH), intravenous clonidine (2μg/kg) and saline infusions were randomly administered under blind conditions to highly anxious depressed and agoraphobic patients (all had panic syndromes) and normal volunteers, in order to assess clonidine's effects on anxiety (Uhde et al. 1980, 1981, in press). As illustrated in Figure 1, the combined group of depressed and panic-phobic patients had significantly decreased ratings of anxiety following clonidine compared to baseline, but no change after placebo-saline infusions. The antianxiety and sedative effects were unrelated. Furthermore, neither clonidine nor placebo influenced baseline ratings of anxiety, as measured by the Spielberger State-Trait Anxiety Inventory in the normal volunteers. This lack of effect on anxiety in the authors' normal volunteers is consistent with the results of Leckman et al. (1980), although the normal subjects in both studies had low baseline ratings of anxiety before clonidine was administered. In another study, Liebowitz and colleagues (1981) administered open oral clonidine to 11 patients with panic disorder or agoraphobia with panic attacks. Four patients demonstrated a good antipanic response after a dose of 200–500 mcg daily. Four patients who initially improved with clonidine experienced a reduction in benefits with chronic administration, and three subjects (including one who reported less severe panic attacks) could not tolerate doses greater than 300 mcg daily. Hoehn-Saric et al. (1981) found clonidine superior to placebo in a double-blind treatment study of 23 patients with generalized anxiety or panic disorders. In the same study, clonidine was found to be as effective in the treatment of patients with generalized anxiety as those with panic attacks. These findings are noteworthy, since previous studies found that panic attacks are blocked by tricyclic antidepressants (Klein 1964) and MAOI (Sheehan et al. 1980) but not by benzodiazepines (McNair & Kahn 1981) or neuroleptics (Klein 1967). More recently, Ko and associates (in press) at Yale found clonidine comparable to imipramine in reducing panic attacks and blocking panic symptoms in patients who were exposed to phobic stimuli which previously elicited panic attacks.

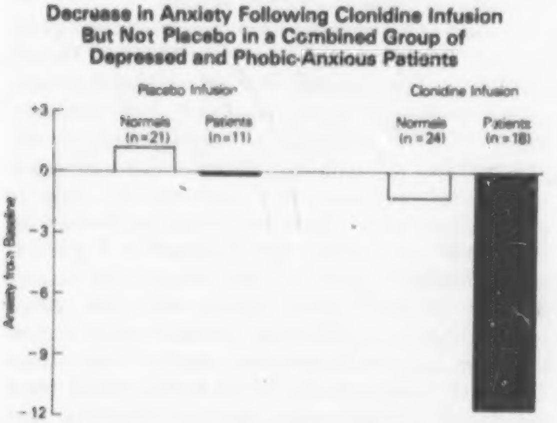

FIGURE 1. In a combined group of depressed ($N = 14$) and agoraphobic patients ($N = 4$), there was a significant decrease in ratings of subjective anxiety following clonidine compared to baseline. (Ten of fourteen depressed and four of four patients with agoraphobia experienced a reduction in anxiety as measured by the Spielberger State-Trait Inventory).

Preliminary data from the authors' double-blind crossover study at the NIMH (Uhde et al. in press) in five patients with panic disorder also suggest that ratings of generalized anxiety and panic attacks decreased after both the acute infusion and the first week of oral administration of clonidine. However, four of the five patients with panic disorder developed tolerance within 3 weeks of chronic clonidine administration (as illustrated in the single case in Figure 2). These findings are consistent with those reported by groups at Columbia (Liebowitz et al. 1981) and Johns Hopkins (Hoehn-Saric et al. 1981). Furthermore, the loss of anxiolytic effects with chronic treatment parallels the time course and development of tolerance to the inhibiting effects of clonidine on the firing rate of the locus coeruleus in animals (Engberg et al. 1982).

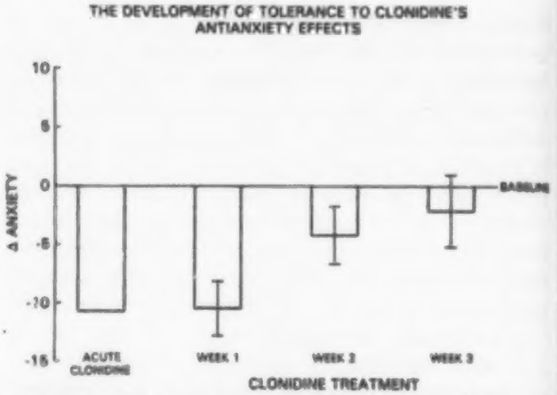

FIGURE 2. In a patient with panic disorder, clonidine treatment initially produced a decrease in self-rated items of anxiety comparable to that achieved by an acute intravenous challenge with clonidine. Ratings of state anxiety obtained during the third week of clonidine administration, however, are not significantly different from baseline-placebo scores, as measured by the Speilberger State-Trait Anxiety Inventory.

In addition to tolerance, clonidine treatment may be associated with a number of untoward side-effects such as drowsiness, sedation, and dry mouth (Hoehn-Saric et al. 1981; Liebowitz et al. 1981; Uhde et al. 1981). The role of the locus coeruleus in fear-related behaviors, arousal, and the sleep-waking cycle may explain the common association between anxiety reduction and sedation for most of the anxiolytic drugs, e.g., benzodiazepines, barbiturates, and meprobamate (Lader 1979).

The combined results of these studies suggest that clonidine may have noteworthy antianxiety effects in depressed, phobic, and panic-anxious patients, as well as patients undergoing opiate withdrawal. In addition, preliminary data suggest that independent measures of nonadrenergic activity may be related to clonidine's antianxiety properties (Ko et al. in press; Uhde et al. 1982, in press). Although clonidine may be less well tolerated by anxious patients than non-anxious hypertensive patients undergoing opiate withdrawal (Uhde et al. 1980a), double-blind comparisons of clonidine to standard drug treatments, e.g., imipramine, are indicated.

Discussion

Anxiety is a subjective experience unique to the human organism. It is impossible to induce in animals a state which, in all its aspects, is equivalent to human anxiety. Nonetheless, animal models may have both practical and heuristic value. For example, the Geller-Seifter test is useful for identifying drugs with antianxiety effects in humans. The disadvantage of this test and other paradigms of behavioral inhibition is that not all drugs with antianxiety (e.g., morphine) or anti-panic (e.g., imipramine) effects in man have anti-punishment effects in animals.

The fear behaviors associated with locus coeruleus function would appear to be a new model relevant for identifying drugs with not only anxiolytic (agents which decrease firing of the locus coeruleus) but also anxiogenic (agents which increase firing of the locus coeruleus) properties. On the basis of its inhibitory effects of the locus coeruleus, clonidine was predicted to have at least transient antianxiety effects in humans (Redmond 1979). Preliminary results would appear to support this hypothesis, since clonidine subsequently has been found to have anxiolytic properties in patients with endogenous anxiety disorders (Hoehn-Saric et al. 1982; Liebowitz et al. 1981; Uhde et al. 1982), depression (Siever et al. 1981; Uhde et al., 1981), and in patients undergoing opiate withdrawal (Uhde et al. 1980a). The noradrenergic locus coeruleus as a functional unit also may be useful as a model for conceptualizing how a single neurotransmitter system might influence opposite emotions on a continuum from "fearlessness" to "panic."

The most problematic aspect of any animal model of human psychopathology is that human emotion is influenced by an intricate and elaborate process of interpretation. That is, human emotion (anxiety) may depend, in part, on the "meaning" of a given stimulus or situation. On the basis of past experience and learning, the biological systems of animals may also be influenced by the "meaning" of a stimulus. The investigations of Segal and Bloom (1976a,b) involving the stimulation of the locus coeruleus during simultaneous recordings from hippocampal neurons may be relevant to this topic. The noradrenergic nucleus locus coeruleus may influence, among other systems, the function of the limbic system, a neuroanatomical substrate which also has been implicated in the modulation of anxiety, mood, and behavior. The locus coeruleus, therefore, may have some capacity for potentiating both inhibitory and excitatory responses which, in turn, may be differentially coded in the same neuron, depending on the relevance of that stimulation to the organism based on prior experience and learning.

Thus, despite the inadequacies of animal models, they may be of both practical clinical value in the development of new drugs and also of heuristic value in conceptualizing possible underlying mechanisms of human anxiety.

Caffeine Consumption and Anxiety: Preliminary Results of a Survey Comparing Patients with Anxiety Disorders and Normal Controls

Jean-Philippe Boulenger, M.D., and Thomas W. Uhde, M.D.[1]

Caffeine, a potent stimulant of the central nervous system (Rall 1980), is widely consumed in America where its estimated daily intake is approximately 200 mg per adult (Gilbert 1976). Symptoms of caffeinism, which are similar to those of anxiety, may develop in individuals who consume more than 500 mg of caffeine daily (Greden 1974). Furthermore, a significant association between caffeine consumption and self-ratings of trait-anxiety and depression has been demonstrated in a group of randomly selected students (Gilliland & Andress 1981). In psychiatric patients, similar results have been reported; i.e., high caffeine consumption was significantly associated with high scores of state-anxiety (Winstead 1976), depression, and both state- and trait-anxiety (Greden et al. 1978). In these studies, however, diagnostic subgroups were not taken into account, a factor which may influence caffeine-related symptomatology both qualitatively and quantitatively. Furthermore, the relationship between caffeine consumption and the incidence of psychopathological symptoms has never been studied in comparison with a control group, a methodological precaution that may be of importance since numerous factors, e.g., age and sex, may influence these two variable (Gilbert 1976; Sartorius 1980).

The authors therefore undertook a survey to study both caffeine consumption and the incidence of various symptoms in patients with anxiety disorders and major affective disorders that fulfilled the Research Diagnostic Criteria (RDC) (Spitzer et al. 1978). These data were compared with those obtained from a group of normal volunteers matched for age and sex. In this paper, as part of this ongoing research, preliminary results obtained in 16 anxious patients and 16 normal controls are presented.

Method

Sixteen anxious patients (15 females, 1 male) with a mean age of 41.2 ± 9.4 years (mean ± S.D.) and 16 age-matched (40.2 ± 10.2 years) and sex-matched controls without significant history of psychiatric illness, were invited to participate in this study. Fourteen patients had both panic and phobic disorders and two patients had both generalized anxiety and phobic disorders according to the RDC. Two patients with symptomatology consistent with a diagnosis of panic disorder were excluded because of concomitant medical illnesses. The 16 normal controls were recruited from the patients' relatives and friends in order to control for sociocultural variables.

Each subject completed a self-rating questionnaire (which may be obtained by writing to the authors), designed by the investigators to assess the consumption of various caffeinated beverages, foods, or drugs and the effects of caffeine on various somatic and psychological symptoms. The consumption of tobacco and medications (including over-the-counter medications) taken more often than twice-monthly was also recorded. The daily caffeine intake was calculated from this questionnaire according to the quantities of caffeine suggested by Gilbert (1976) for different

beverages, i.e., dripped coffee: 110 mg/cup; percolated coffee: 75 mg/cup; instant coffee: 65 mg/cup; decaffeinated coffee: 2 mg/cup; tea: 30 mg/cup; cola drinks: 40 mg/12 oz.; cocoa: 20 mg/cup. The caffeine intake related to drugs or chocolate bars (20 mg/bar) was added to the previous total.

In addition, the Spielberger State-Trait Anxiety Inventory (STAI) (Spielberger et al. 1970) and the Hopkins Symptom Checklist (HSCL-90) (Derogatis et al. 1976) were administered. The following subscales were derived from the HSCL-90 items: General Symptomatic Index (GSI), Positive Symptom Distress Index (PSDI), anxiety and phobic factors (Derogatis et al. 1976), phobic-anxiety, agitated depression, retarded depression, interpersonal sensitivity, somatization, obsessive-compulsive, and anger-hostility factors (Lipman et al. 1979).

Results

Daily Caffeine Consumption

The anxious patients consumed 185.9 ± 157.9 mg/day (mean ± S.D.) of caffeine, whereas the normal controls consumed 216.2 ± 174.9 mg/day (*t*-test, N.S.). There was no relationship between daily caffeine consumption and age, smoking habits, drug, or psychiatric treatments. Of all the individuals who no longer drank coffee, a significantly greater number of anxious patients (7 of 9) reported doing so because of the induction of anxiety, tension, and/or nervousness compared to the normal controls (2 of 5) (chi-square, $p < 0.05$). With the exception of one patient with panic disorder, all subjects were still consuming significant amounts of other caffeinated beverages.

State- and Trait-Anxiety

As expected, the anxious patients had significantly higher ratings of state-anxiety (50.19 ± 10.26) and trait-anxiety (54.14 ± 10.85) compared to the normal controls (state = 32.09 ± 4.21, $p < 0.001$; trait = 33.36 ± 5.18, $p < 0.0001$). Furthermore, in the anxious patients there was a significant positive correlation between daily caffeine consumption and trait-anxiety ($r = 0.90$; $p = 0.0001$) but not state-anxiety ($r = 0.007$; N.S.) (*see* Figure 1)

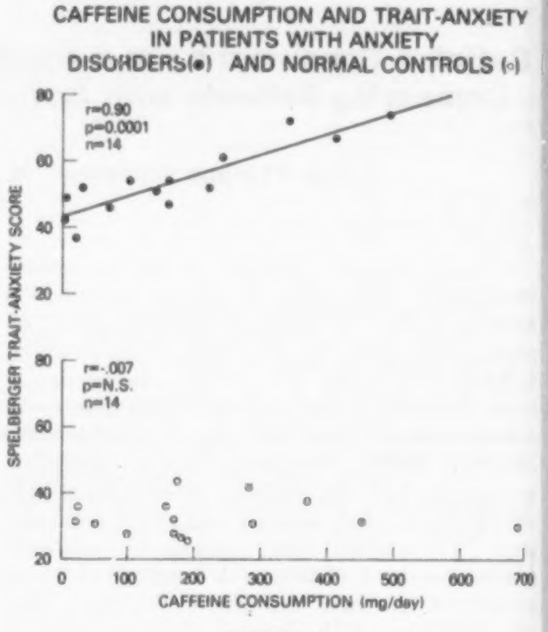

FIGURE 1

Subscales Derived From the HSCL-90

As expected, the anxious patients had significantly higher scores on the various subscales of the HSCL-90 compared to the normal controls, as indicated by the GSI (patients 1.55 ± 0.69; controls 0.38 ± 0.36; *t*-test $p < 0.0001$) and the PSDI (patients 2.31 ± 0.51; controls 1.43 ± 0.34; *t*-test $p = 0.0001$) indices. There was no relationship between caffeine consumption and the HSCL-90 subscales in the control group. However, in the anxious patients there was a significant positive relationship between caffeine consumption and the following subscales: retarded depression ($r = 0.80$; $p = 0.0003$; GSI ($r = 0.77$; $p = 0.0005$); obsessive-compulsive ($r = 0.74$; $p = 0.002$); hostility ($r = 0.72$; $p = 0.002$); somatization ($r = 0.68$; $p = 0.005$); PSDI ($r = 0.68$; $p = 0.006$); interpersonal sensitivity ($r = 0.61$; $p = 0.016$); agitated depression ($r = 0.53$; $p = 0.043$). Furthermore, it is noteworthy that in

FIGURE 3

the anxious patients there was a significant positive correlation between caffeine consumption and those factors which primarily reflect generalized anxiety (anxiety: $r = 0.54$; $p = 0.038$) but not those which primarily reflect agoraphobia (phobic-anxiety: $r = 0.19$; N.S.) (*see* Figures 2a and 2b).

Caffeine Effects on Various Psychological and Somatic Symptoms

All subjects were asked to rate changes, if there were any, in their anxiety, alertness, sleep, and mood induced by drinking one cup of coffee, on a 4-item scale. As illustrated in Figure 3, the consumption of even one cup of coffee was associated with more intense ratings of anxiety, insomnia, and alertness in the anxious patients compared to normal volunteers.

Because anxiety and insomnia may be present at baseline before any coffee consumption, subjects were asked to indicate whether coffee induced or increased symptoms already present. Among those for whom coffee induced symptoms, i.e., those having a baseline level equal to zero, the caffeine-induced effects were greater in the patients compared to the normal controls, although this effect was nonsignificant.

All subjects were also asked to check, on a list of 26 symptoms, those items they associated with the consumption of coffee and to rate their intensity on a 5-point scale (0-4). For the anxious patients the caffeine-induced symptoms reported to have a mean score > 1 were, by order of decreasing intensity (mean ± S.D.): tension, nervousness (1.87 ± 1.36); anxiety (1.69 ± 1.49); insomnia (1.69 ± 1.70); increased urination (1.27 ± 1.53); increased motor activity (1.12 ± 1.36); tremors (1.12 ± 1.59); diarrhea (1.00 ± 1.51). For the normal controls, these caffeine-induced symptoms were: insomnia (1.31 ± 1.30) and increased motor activity (1.19 ± 1.28). The intensity of the following caffeine-induced symptoms was significantly higher in the patient group (*t*-tests): anxiety ($p = 0.004$); tremors ($p = 0.016$); muscle tension ($p = 0.028$); panic attacks ($p = 0.041$); lightheadedness ($p = 0.044$); diarrhea ($p = 0.046$).

Discussion

The present investigation is the first to survey the consumption and effects of caffeine in a group of patients suffering from phobic disorders associated with either panic or generalized anxiety symptoms. In this group the daily caffeine consumption (185 mg/day) was nonsignificantly lower than in a control group (215 mg/day) matched for age and sex. A similar result had been found by Greden et al. (1981) when comparing the caffeine consumption of hospitalized psychiatric patients to that of hospitalized nonpsychiatric patients. In the present study the caffeine consumption found in both groups was similar to the average daily consumption in American adults reported by Gilbert (1976), i.e., 200 mg/day.

A major finding of this study was that a highly significant positive correlation ($r = 0.90$; $p < 0.0001$) existed between the daily caffeine consumption and the scores of trait-anxiety within the patient group but not in the control group (Figure 1). Such a correlation would not appear to be related to the consumption of benzodiazepines by the patients even though caffeine has been shown to antagonize the biochemical (Boulenger et al. 1982) and pharmacological (File et al. 1982) effects of benzodiazepines in humans. Only five patients who were caffeine users (10-240 mg/day) were also taking psychotropic drugs (all being minor tranquilizers). Thus, our preliminary results suggest that an increased sensitivity to the effects of caffeine may exist in anxious patients as composed to normal controls, a finding similar to that described for other compounds, e.g., lactate, epinephrine, or isoproterenol (for review, *see* Pitts & Allen 1979). This increased sensitivity would explain in part why significantly more anxious patients than controls have given up coffee because of its central nervous system stimulant properties, and why the caffeine-induced effects appear to be significantly more severe in the former than in the latter (Figure 3). It is also possible that the higher baseline levels of anxiety and/or insomnia of the anxious patients may have contributed to these results. Double-blind, caffeine-placebo challenges are indicated in order to determine whether anxious patients are truly more susceptible to caffeine-related anxiety symptoms than controls.

In contrast to trait-anxiety, state-anxiety was not related to caffeine consumption in either the anxious patients or the normal controls. Such a result may not be surprising since it is more likely that habits of caffeine consumption might be related to trait-anxiety (presumably a stable characteristic) rather than to state-anxiety (anxiety which fluctuates and reflects situational factors at the time of testing) (Spielberger et al. 1970).

Despite the use of similar rating scales (STAI), previous studies have reported conflicting results concerning the relationship between caffeine consumption and state- and trait-anxiety. While in normal students high caffeine consumption is asssociated with trait-anxiety but not state-anxiety (Gilliland & Allen 1981), studies of unspecified psychiatric inpatients have reported an association with state-anxiety alone (Winstead 1976) or both state- and trait-anxiety (Greden et al. 1978).

In addition to trait-anxiety, several HSCL-90 subscales were found to be significantly and positively correlated with caffeine consumption in the patient group but not in the controls. Such an association may be related to the increase of trait-anxiety found with increasing caffeine consumption or to a nonspecific and more generalized increase in the level of psychopathology. Other studies demonstrating a significant correlation between caffeine consumption and both anxiety and depression (Gilliland & Andress 1981; Greden et al. 1977) have also raised this problem. The extension of the present survey to include a group of patients with affective disorders should clarify the possible relationship between caffeine consumption and other types of psychiatric disorders.

Another interesting finding is the relationship between caffeine consumption and the scores of the HSCL-90 "anxiety" factor but not the "phobic-anxiety" factor (Figure 2). The "anxiety" factor, reflecting mainly generalized anxiety symptoms appears to be sensitive to caffeine effects in a dose-related manner while the "phobic-anxiety factor," reflecting mainly agoraphobic symptoms, is not significantly affected by caffeine consumption. These data are consistent with the description by Klein (1980) of agoraphobia as a distinct clinical entity with different clinical characteristics, symptoms, evolution, and pharmacologic response to antidepressant treatments.

In conclusion, the present study suggests that caffeine consumption is positively correlated with trait-anxiety in patients with phobic disorders associated with either panic or generalized anxiety disorders. Such a correlation may be related to an increased sensitivity of these patients to the effects of caffeine, particularly those symptoms related to generalized anxiety. In contrast, symptoms of agoraphobia do not appear to be influenced by caffeine consumption, a finding which supports its description as a distinct clinical entity. The correlation between the amount of caffeine consumed and other psychopathological factors such as depression raises the problem of the specificity of caffeine's effects on psychiatric disorders. Further surveys, including the use of caffeine challenge paradigms in various psychiatric patients, should help to clarify these relationships.

New Anxiolytics: Are They Really New?[1]

David J. Greenblatt, M.D.,[2] and Richard I. Shader, M.D.[2]

The pharmaceutical industry continues its search for more specific and more effective pharmacologic treatments of anxiety. With a few recent exceptions (Rickels 1981), the great majority of new anxiolytics are of the benzodiazepine category. Benzodiazepines as a class of compounds clearly have increased the overall efficacy of anxiolytic pharmacotherapy relative to drugs available prior to 1960, and also have greatly increased the safety of such treatment. However, numerous benzodiazepines are clinically available as anxiolytics, and although superior as a class of drugs, meaningful differences among various drugs within the class are at best subtle. It is of great importance to pharmacologists, practicing physicians, and members of institutional formulary committees that clinical and pharmacokinetic characteristics of new benzodiazepine anxiolytics be carefully and critically evaluated before promotional claims of newness or uniqueness are accepted as valid. This paper briefly considers the properties of several new benzodiazepine anxiolytics, together with an assessment of their potential role in the pharmacotherapy of anxiety.

Halazepam and the Parade of Desmethyldiazepam Precursors

Halazepam (Paxipam) was recently introduced as a benzodiazepine anxiolytic in the United States (Figure 1). Clinical trials hav demonstrated its comparability to other standar benzodiazepine antianxiety agents, both in term of efficacy and side effects (Rickels et al. 1977 Fann et al. 1982). The pharmacokinetic profile o halazepam, however, reveals interesting properties. Many benzodiazepines are precursors o desmethyldiazepam, being partly or completel transformed to this metabolic product (Figure 2) Two benzodiazepines already available in th United States—clorazepate and prazepam—are in fact, nearly completely transformed t desmethyldiazepam prior to reaching the systemi circulation (Allen et al. 1980; Shader et al. 1981 Greenblatt et al. 1981a). Current data o halazepam appears to put this drug in a simila category. After a single oral dose of halazepam the intact drug appears in systemic blood onl transiently and at relatively low levels, bein rapidly transformed to the principal metaboli desmethyldiazepam (Figure 3). Due to its ver long elimination half-life (Allen et al. 1980 Greenblatt et al. 1981a; Shader et al. 1981) desmethyldiazepam persists in blood much longe than halazepam. During multiple-dose therap with halazepam, the parent drug will accumula minimally, whereas the major metabolite will accumulate extensively, consistent with its very lon elimination half-life.

Since halazepam serves mainly as anothe precursor of desmethyldiazepam, it is difficult t conclude that this drug would add meaningfull to the already available armamentarium of lon half-life accumulating benzodiazepines such a diazepam, clorazepate, or flurazepam (Greenblatt et al. 1981a). Thus, halazepam serves as a example of a drug for which careful pharmacokinetic studies can readily establish its likel role in clinical practice.

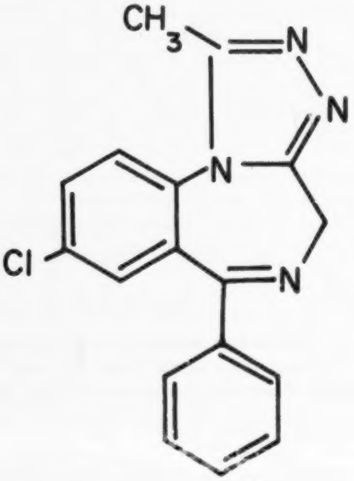
lprazolam: The Tirazolo Benzodiazepines

Another important research strategy for the levelopment and evaluation of new ben-odiazepines involves compounds whose structure leviates from the familiar 1,4-benzodiazepine onfiguration. The most important of these com-ounds is alprazolam, in which a triazolo ring is affixed to the positions previously designated as 1 and 2 (Figure 4). In clinical studies of anxiolytic efficacy in patients with neurotic anxiety, alprazolam performs similarly to other comparison benzodiazepines (Cohn 1981). An apparently unique property of this compound has been suggested by studies comparing its clinical efficacy to that of tricyclic antidepressants in patients with endogenous depression (Fabre & McLendon 1980). The results available to date suggest that alprazolam may have antidepressant as well as anxiolytic effects. If such findings are replicated in subsequent trials, this would be a unique and important property, since alprazolam has a relatively benign benzodiazepine-like profile of side effects as opposed to the more important and potentially serious side effect profile of the tricyclic antidepressants. Consistent with these reports are other preliminary findings suggesting that alprazolam may have efficacy in the treatment of panic attacks and related disorders.



ALPRAZOLAM

FIGURE 4. Structural formula of alprazolam.

None of these apparently unique clinical properties of alprazolam could have been predicted based on its pharmacokinetic profile (Greenblatt et al. 1982a). The metabolic disposition of alprazolam involves hepatic oxidation, yielding hydroxylated metabolites which reach the systemic circulation in negligible quantities. Therefore, essentially all of the clinical activity of alprazolam is attributable to the parent compound. The apparent elimination half-life of alprazolam in humans usually ranges from 8 to 16 hours (Figure 5). As in the case of other benzodiazepines transformed by oxidation (Greenblatt et al. 1982b), the half-life is prolonged in elderly as opposed to young males due to reduced oxidizing capacity in the elderly male population.

In mechanistic terms, it has not established why alprazolam should have antidepressant as well as anxiolytic properties. It may well be that other triazolo benzodiazepines such as triazolam or estazolam share similar properties.

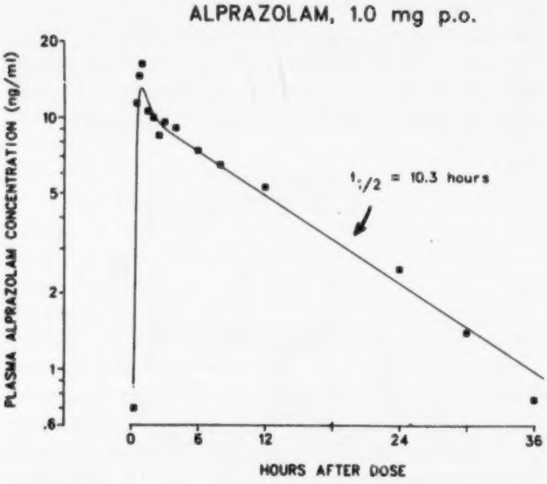


FIGURE 5. Plasma concentrations of alprazolam in a volunteer who ingested a single 1-mg oral dose. Solid line is the computer-determined pharmacokinetic function of best fit.

Clobazam: A Shift of the Nitrogen

Clobazam is a 1,5-benzodiazepine derivative, and thereby differs from other benzodiazepines in the position of the nitrogen substituents on the central nucleus (Figure 6). Its anxiolytic efficacy has been clearly established in many controlled trials, and the drug is extensively used as an antianxiety agent in Europe (Brogden et al. 1980).

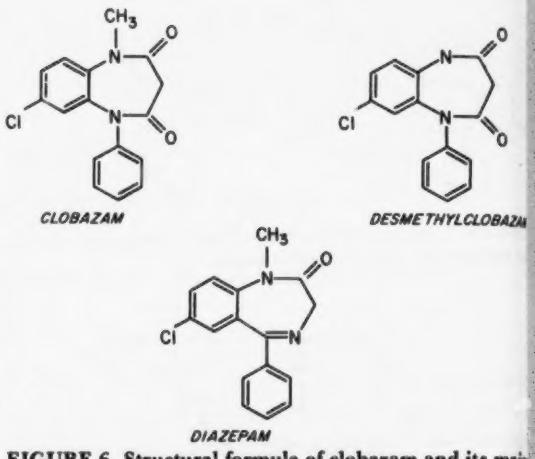

FIGURE 6. Structural formula of clobazam and its maj metabolite, desmethylclobazam. Also shown for com parison purposes is the structure of diazepam.

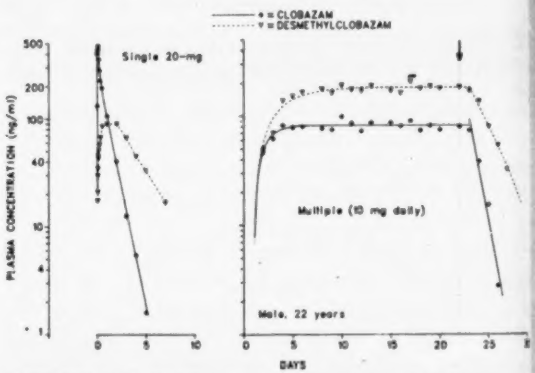

FIGURE 7. Left: Plasma concentrations of clobazam an desmethylclobazam in a volunteer who ingested a sing 20-mg oral dose of clobazam.
Right: Concentrations of clobazam and desmethyl diazepam in the same volunteer who ingested 10 mg o clobazam once daily for 22 days. Note the pattern of ac cumulation as well as washout for both compounds aft the last dose (arrow).

Despite the different positioning of the nitrog atoms, the metabolic profile of clobazam i humans closely resembles that of diazepam. Biotransformation of clobazam proceeds b hepatic N-demethylation, yielding the phar macologically active metabolite, desmethyl clobazam (Greenblatt et al. 1981b; Tedeschi et al 1981). This is entirely analogous to the situatio with diazepam, which is transformed to the activ substance desmethyldiazepam. For bot clobazam and diazepam, the elimination half-life of the metabolite is greater than that of the parent drug, and the clearance of the metabolic product is lower than that of the parent drug. For this reason, concentrations of desmethylclobazam after single oral doses of the parent drug persist in plasma considerably longer than those of clobazam (Figure 7). During multiple-dose therapy, accumulation of clobazam and desmethylclobazam is extensive, with levels of the metabolite generally exceeding those of the parent compound (Figure 7). After discontinuation of therapy, both compounds wash out from plasma at a slow rate, although desmethylclobazam persists longer than the parent drug. All of these characteristics are highly analogous to the situation seen during single and multiple dosing with diazepam.

Despite claims to the contrary, the kinetic similarity of clobazam and diazepam makes it unlikely that clobazam would provide meaningful advantages in clinical practice over what is already available from diazepam.

Conclusion

Evaluation of new anxiolytics in clinical practice—in particular, benzodiazepine anxiolytics—should involve careful metabolic as well as clinical testing. Clinical properties of specific compounds may emerge which are completely unrelated to or are not predicted by pharmacokinetic profiles, as is the case with alprazolam. In other cases, such as with halazepam and clobazam, pharmacokinetic similarities to already available benzodiazepines suggest that these drugs are unlikely to provide meaningful additional benefits. Multidisciplinary evaluation of new anxiolytics is essential to provide the most comprehensive picture of what can be expected from such agents.

Differentiating Depression and Anxiety: Is It Possible? Is It Useful?[1]

Edna B. Foa, Ph.D.,[2] and Uriel G. Foa, Ph.D.[3]

The terms "depression" and "anxiety" have been used to denote mood states as well as labels for diagnostic categories. As a mood state, depression is characterized by sadness, and anxiety by fear. When these mood states are of high intensity, long duration, and/or frequent, they are considered psychopathological signs or symptoms. When intense sadness appears in combination with other signs or symptoms such as sleep disturbance and loss of appetite, a diagnosis of depression is assigned. When a person with a fear mood state also exhibits autonomic arousal and/or avoidance behaviors, he or she will be diagnosed as "anxious." Thus, "depression" and "anxiety" have been used to denote two distinct syndromes or diagnostic entities.

The relationship between anxiety and depression as diagnostic categories has been the subject of controversy for many years. Some investigators believe that the two syndromes cannot or should not be distinguished, since they constitute manifestations of the same disturbance; others hold the contrary position. A recent comprehensive review of the relevant literature (Roth & Mountjoy 1982) essentially leaves the question open.

The purpose of this paper is twofold: To consider conceptual and methodological problems in the study of the relationships between anxiety an depression, and to present data bearing on thi relationship in obsessive compulsives who wer treated with behavior therapy.

Definition and Measurement

The symptoms and signs of the two psycho- pathological conditions can be divided into thre classes: 1) signs which are specific to anxiety; 2 those which are specific to depression, and 3 signs which are common to both syndromes. A present, the diagnostic criteria used to classify a patient as depressive also include signs of anxiety Thus, the definition of the two syndromes are no independent of one another. This is also true o the instruments which have been developed t measure depression and anxiety. Having been influenced by the traditional diagnostic criteria o the two syndromes, they reflect the overlap between them. The Hamilton Depression Scale, fo example, includes items on insomnia, agitation psychic anxiety, somatic anxiety, and somati symptoms, all contributing to the total score o depression. It is not surprising that this score wil correlate highly with measures of anxiety whic also include somatic complaint, agitation, and feelings of doom. The strong influence of the traditional overlay between the two syndromes on the measurement of depression is demonstrated in the argument by Snaith et al. (1971) that the Wakefield inventory constituted a better measurement of depression than the Beck and Zung inventories, since the latter failed to include items dealing specifically with anxiety. The remedy offered for this omission was an assessment tool of depression loaded with items pertaining to anxiety

Snaith et al.'s comments exemplify the absence of conceptual distinction between anxiety and depression which obscures the meaning of the high correlation between the two, often found when assessment by self-reports and by clinical observations was employed. What do these correlations represent? Do they reflect a high joint occurrence between anxiety and depression or are they merely an artifact of the overlap between the definitions and the measurements of the two syndromes?

Another conceptual and methodological problem is embedded in the fact that most instruments designed to measure anxiety or depression yield a single global score. Yet neither of the two is a unitary concept. Rather, each is composed of behavioral, psychophysiological, biochemical, and cognitive-emotional components which are imperfectly intercorrelated. The nature and the degree of the relationship between depression and anxiety may vary greatly, depending on the specific component under investigation. For example, Kelly and Walter (1969) found that the forearm blood flow of nonagitated depressives was less than that of normals, whereas agitated depressed and anxious patients showed increased blood flow. However, when self-reports of anxiety level were examined, the order among the groups changed. Agitated depressives evidenced the lowest level of anxiety, while nonagitated patients rated themselves to be as anxious as those in the anxious group. Thus, in investigating the relationships between anxiety and depression, it seems necessary to study multiple components with the aim of identifying *patterns* of relationships between the two concepts, rather than expecting unidimensional solutions.

The independent definitions of depression and anxiety should each include several component elements. Given the state of the art, however, it seems convenient to start by identifying criteria for classification of the cognitive and the behavioral components which are central to each of the two concepts, and to omit characteristics which are common to both. Measurements for depression and anxiety should be guided by these definitions. Having developed such measurements, we will be better equipped to investigate the relationships between anxiety and depression in various clinical populations, to observe possible changes in these relationships over time, or to examine the effects of anxiety and depression on treatment outcome. This line of investigation will provide an answer to the second question posed: Is the distinction between anxiety and depression useful? Such a distinction is of merit only if there is evidence for different aetiologies, treatments of choice, or treatment outcomes for the two categories.

Differences and Similarities

Notwithstanding the limitation discussed above, the data available point to some differences as well as to certain similarities between anxiety and depression. Not surprisingly, these findings have stoked the fires of proponents of separation (e.g., Roth et al. 1972) as well as of those arguing for unification of the two concepts (e.g., Lewis 1966). Let us consider this evidence briefly.

Psychophysiological Measures

A mixed picture of similarities and differences between depression and anxiety emerges from psychophysiological observations. Lader and his colleagues (Lader 1967, 1976; Lader et al. 1967; Lader & Wing 1964, 1966) demonstrated that patients with anxiety states showed high levels of electrodermal activity and slow habituation of skin conductance responses to repeated auditory stimuli. They also found that complex phobics (i.e., agoraphobics, social phobics, and anxiety states) evidenced more baseline arousal than monophobics with respect to both electrodermal activity and pulse rate; the monophobic group did not differ from normals.

When depressed patients were divided into subgroups of retarded and agitated depressives, differences in electrodermal activity also emerged (Lader & Wing 1969). The agitated depressed patients (who manifest intense anxiety) were more aroused than the retarded groups and, like anxious patients, they habituated more slowly to auditory stimuli than did normals. The retarded group showed almost no electrodermal activity. A similar picture emerged from observations of the cardiovascular responses. As mentioned earlier, Kelly and Walter (1969) found a lower level of forearm blood flow in nonagitated depressed patients than in the agitated depressives. Likewise, Lader and Wing (1969) reported an increase in pulse rate over normals in agitated but not in retarded depressives. Investigating evoked responses in depressed and anxious patients, Shagass (1955) applied photic stimulation at 10 and 15 Hz to normals, anxiety states, psychoneurotic depressive patients, and psychotic depressives. The ratio of responses at 15 Hz to those detected at 10 Hz was highest in the anxious state patients and lowest for both depressive groups with normals occupying an in between position. The difference among the groups was attributed to differences in the amount of harmonic activity induced by the photic stimulation; again, depressives showed less activity and anxious patients evidenced more activity than normals. It seems, then, that depression suppresses psychophysiological activity whereas anxiety increases it. As stated by Lader (1975), the psychophysiological literature favors a distinction between anxiety and depression "but only if particular care with subgrouping of patients is exercised" (p. 129).

Joint Occurrence

The view that depression and anxiety should be considered a unitary syndrome has been bolstered by the finding that a high proportion of neurotic patients, especially those who are not severely impaired, show both anxiety and depression. So much so that the term anxiety-depression has been proposed by several authors to denote a distinct diagnostic class (e.g., Cooper & Sylph 1973; Snaith 1981). Support for the unitary view is provided by the fact that a relatively high percentage (24 percent) of those who had been diagnosed as being in an anxiety state were rediagnosed several years later as depressives (Kandell 1974). This finding points to the existence of a relationship between anxiety states and depression. However, the fact that only 2 percent of those who were first diagnosed as depressed became anxious at a later time indicates that the two syndromes are distinct. This latter view is further supported by other investigations.

In a series of studies, Roth and his colleagues (Gurney et al. 1972; Roth et al. 1972) examined differences and similarities between patients diagnosed as anxious and those labeled depressed. A first bipolar component of anxiety vs. depression emerged when a principal component analysis was performed on the data. Moreover, the presence of an anxiety syndrome decreased the likelihood that a depressive syndrome would be detected in the same patient and vice versa. These results offer strong support for the separatist camp; they should, however, be considered with caution since the studies suffer from several methodological flaws.

Fleiss et al. (1971), in studying 500 admissions to New York and London mental hospitals, found depression and phobic anxiety to be distinct factors. In the total sample 14 subjects were classified as suffering from anxiety neurosis and 63 were neurotic depressives. When the scores of these patients on depression and on anxiety were examined, the authors found that both groups were equally depressed; but anxiety scores differentiated the two, being higher in the anxiety group. Further support for the separatist view was provided by Prusoff and Klerman (1974) as well as by Downing and Rickels (1974) who were able to separate anxiety from depression on the Hopkins Symptom Checklist. However, a relatively large overlap betwen the two groups existed (25 to 40 percent) and high correlations between anxiety and depression were consistently found. Interestingly enough, Klerman (1980) quoted the above studies in support of the distinction between depression and anxiety syndromes whereas Marks (in press) referred to these same studies when questioning the usefulness of such a separation.

A distinction between anxiety and depression has also emerged from a study on the effects of behavioral treatment of obsessive-compulsives conducted by the first author, (e.g., Foa & Goldstein 1978; Foa et al. 1980; Steketee et al., in press). In the course of evaluating the effectiveness of behavioral treatment, both the patients and an independent assessor rated depression and anxiety *mood states* on 9-point scales which were developed at the Maudsley Hospital in London (Watson et al. 1971). Depression was defined as loss of interest, crying, pessimistic outlook, sadness, and suicidal thoughts. Anxiety was defined as subjective tensions, autonomic arousal, and motor restlessness. There was almost no overlap between the guidelines given to the raters about the type of emotions and behavior they were to consider for determining the scores of the two variables. Data on levels of depression and anxiety in 71 obsessive-compulsives were thus obtained.

To investigate the joint occurrence of the two variables, patients were divided into three groups with respect to their level of depression. Those whose level of depression was greater than one standard deviation (SD) above the mean were considered "highly" depressed, those whose level was one SD below the mean were labeled "mildly" depressed, and the remainder were classified as "moderately" depressed. The same was done with regard to anxiety. The results were then cross-tabulated. They are given in Table 1.

A strong relationship emerged ($X^2(4) = 16.94$, $p < .01$). However, inspection of the joint occurrence of these variables revealed an interesting pattern. Only 50 percent of the sample fell on the diagonal where the degree of depression and of anxiety were equal. Those who were highly depressed were almost always highly anxious. On the other hand, most highly anxious patients were only moderately depressed. Further, mild depression was associated with *either* moderate or low anxiety. The moderately depressed patients were *either* very anxious or moderately anxious. This asymmetry in the relationships between levels of depression and levels of anxiety suggests that the authors tapped two distinct phenomena and that the relationship found does not merely represent a reliability score for two measures of the same variable.

Table 1

Joint Distribution of Anxiety and Depression Levels in Obsessive-Compulsives Before Treatment

Anxiety	Depression			
	High	Moderate	Mild	Total
High	8	20	2	30
Moderate	1	19	6	26
Mild	0	8	7	15
Total	9	47	15	71

Differences in Responsiveness to Behavioral Treatment

An important criterion favoring a distinction between two conditions is whether they respond differently to treatment. The literature on the effects of psychopharmacological agents on depressed and anxious patients has yielded a mixed picture in this regard and will not be discussed here. Instead, the authors shall consider the differential effects of pretreatment depression and anxiety mood states on effectiveness of behavioral techniques (i.e., exposure and response prevention) with obsessive-compulsive ritualizers. These techniques have been considered the treatment of choice for this disorder (cf. Foa & Steketee 1979). However, several authors suggested that obsessive-compulsives with marked depression do not benefit from treatment by exposure and response prevention as much as those with moderate or mild depression. Indeed, Foa et al. (1982) found that marked depression impeded the immediate effectiveness of behavioral treatment and resulted in a significantly higher rate of relapse.

In a subsequent analysis with a larger sample of 71 patients, the relationship of anxiety as well as of depression to treatment outcome were examined immediately following treatment and at 11 months followup (on the average). The scores for obsessions and compulsions as rated by an independent assessor were combined to yield one score of obsessive-compulsive symptomatology. This score was then converted into a percentage score of change from pretreatment baseline. On the basis of this score, the patients were divided into three groups: those who improved 70 percent or above were labeled "much improved"; those with improvement of 30 to 69 percent were labeled "moderately improved"; patients who failed to show improvement of more than 29 percent were considered "failures". This analysis was performed separately for outcome at posttreatment and at followup.

Prediction from Depression

The relationship between initial depression and treatment outcome was examined with a one-way analysis of variance (ANOVA). Significant differences were detected at posttreatment [$F(2,68) = 6.77$, $p < .002$]. The mean depression scores for those who succeeded, improved, or failed to benefit from behavioral treatment were 3.15, 4.64, and 5.19, respectively. Posthoc pairwise comparisons using the Bonferoni *t*-method revealed that the much improved group was significantly less depressed than the moderately improved group ($t = 3.14$, *d.f.* 68, $p < .01$) than those who failed ($t = 2.88$, *d.f.* 68, $p < .05$). At followup those who were treated successfully were significantly less depressed than the failures ($t = 2.92$, *d.f.* 51, $p < .05$), but did not differ from the moderately depressed patients.

The relationship between depression and treatment outcome was further explored by cross-tabulating the data at posttreatment and at followup. These results are given in Tables 2 and 3.

Table 2

Comparison of Initial Depressed Mood with Outcome at Posttreatment

Outcome	Depression High	Moderate	Mild	Total
Much Improved	1	17	12	30
Moderately Improved	7	23	2	32
Failure	2	7	0	9
Total	10	47	14	71

Table 3

Comparison of Initial Depressed Mood with Treatment Outcome at Followup

Outcome	Depression High	Moderate	Mild	Total
Much Improved	1	17	11	29
Moderately Improved	2	5	2	9
Failure	5	14	0	19
Total	8	36	13	57[a]

[a] At the time this analysis was performed, 14 of the 71 patients had not yet been followed up.

A chi-square performed on these data indicated significant differences at both posttreatment ($X^2(4) = 15.99$, $p = .003$) and at followup ($X^2 = 12.54$, $p = .01$). Inspection of these tables indicates that immediately after 2-3 weeks of daily 2-hour sessions by exposure and response prevention, 12 of the 14 patients who were mildly depressed were much improved, and none failed. The highly depressed groups had one success and two failures; the majority of the patients in this group were moderately improved (*see* Table 2). This pattern became more clear at followup (*see* Table 3). Of the eight patients with marked depression five were failures; none of the mildly depressed patients was a failure and 87 percent were highly improved. Thus, the level of depression at the extremes predicted response to treatment. Patients with marked depression were likely to fail to benefit from behavioral treatment; those with mild or no depression were highly likely to benefit from this treatment.

Table 4

Comparison of Initial Anxious Mood with Outcome at Posttreatment

Outcome	Anxiety High	Moderate	Mild	Total
Much Improved	10	9	12	31
Moderately Improved	16	13	2	31
Failure	5	3	1	9
Total	31	25	15	71

Table 5

Comparison of Initial Anxious Mood with Outcome at Followup

Outcome	Anxiety High	Moderate	Mild	Total
Much Improved	11	7	11	29
Moderately Improved	3	3	3	9
Failure	11	8	0	19
Total	25	18	14	57[a]

[a] At the time this analysis was performed, 14 of the 71 patients had not yet be followed up.

Prediction from Anxiety

A different picture emerged for the investigation of the relationship between anxiety and treatment outcome, although anxiety was also found related to responsiveness to behavioral treatment. (At posttreatment $F[2,68] = 4.99$, $p < .01$; a followup $F[2,51] = 3.24$, $p < .05$.) When degree o anxiety was cross-tabulated with degree of success in behavioral treatment, a significant relationship was again detected. (At posttreatment

$X^2(4) = 10.53$, $p < .03$; at followup $X^2(4) = 9.56$, $p = < .05$.)

However, the pattern for anxiety as a predictor of treatment outcome differed from that for depression. At posttreatment (*see* Table 4) one third of the highly anxious patients were much improved, although their chances were not as good as those who were initially mildly anxious. Among the latter, most were much improved and only one failed. A similar pattern emerged at followup (*see* Table 5).

In summary, mild depression predicted success and high depression predicted failure of behavioral treatment with obsessive-compulsives. By contrast, even a high level of anxiety was associated with good response to treatment. This pattern became more pronounced at followup (*see* Tables 3 and 5). Marked depression predicted failure, whereas high anxiety was equally associated with success and with failure.

Conclusion

The mood states of anxiety and depression have yielded a somewhat different prognosis in the study reported here, despite the crude measurements which have been employed. The existence of such a difference indicates that a distinction between depression and anxiety might be useful for predicting the outcome of behavioral treatment. Paradoxically, such a distinction is also a *sine qua non* for the investigation of the empirical joint occurrence of anxiety and depression, an issue that has gained much attention in the psychiatric literature. Only definitions which are independent of one another will lead to the construction of instruments of depression and anxiety which will not overlap each other. Only such instruments may yield valid data for the understanding of the relationship between two concepts.

Each instrument should include items from several components (at least from the cognitive and behavioral domains) and each should exclude items which are common to the two syndromes. In essence, then, the investigation of the relationship between depression and anxiety will involve comparisons of several clusters of observations rather than of two single indices composed of a variety of symptoms which has been forcibly combined. The results so obtained will hopefully contribute to a more lucid conceptualization of the two syndromes. As the relationship between concepts and data is a reciprocal one, more precise concepts lead to better measurements which, in turn, yield information that further clarifies theoretical issues.

Differentiating Anxiety and Depression in Anxiety Disorders: Use of Rating Scales

Ronald S. Lipman, Ph.D.[1]

Both anxiety and depression have been conceptualized as normal affects or moods, as symptoms (when their intensity or duration persists beyond "normal" limits), as syndromes (when a cluster of co-occurring symptoms are identified), and as diagnostic entities (when notions of differential etiology, prognosis, and/or treatment response as well as boundaries between mental disorders are employed) (Diagnostic and Statistical Manual-III 1980; Lehmann 1966).

This paper will focus on differentiating anxiety and depression at the level of syndromes and diagnoses. It should be made clear that while some writers consider anxiety and depression as phenomenally indistinguishable (e.g., Lewis 1966), the overwhelming consensus in the field is that these two affective disorders are separable and, indeed, that neither anxiety nor depressive disorders are themselves single mental disorders. This area has recently been reviewed by McNair and Fisher (1978) and, indeed, the reader is probably familiar with both statistical typologies such as Overall et al. (1966) (based on Brief Psychiatric Rating Scale scores on Anxious, Hostile, Agitated, and Retarded Depression), and clinical typologies such as Klein's (1974) concept of reactive, endogenomorphic, and neurotic depression. Since the Diagnostic and Statistical Manual-III (DSM-III) (1980) differentiates among and between anxiety disorders and affective disorders, which subsume depresssion, it is probably worthwhile to examine the DSM-III classification of primary anxiety disorders. In this regard, DSM-III, as a result of the research of Klein (1978), differentiates between Panic Disorder and Generalized Anxiety Disorder, both characterized by free or manifest anxiety, and Phobic and Obsessive-Compulsive Disorders, where the patient goes to extremes to avoid experiencing the anxiety of either the dreaded object or situation or of the resisted obsession or compulsion. A good description of Phobic and Anxiety States, based on DSM-III, has been developed by Davis et al. (1981) and is presented in Table 1.

Table 1

Diagnostic Description of Phobic Disorders and Anxiety State

Sudden spontaneous unexplained panic attack characterized by feeling of terror, autonomic symptoms of anxiety, and flight response

Symptoms during an attack may include:

- Anxiety, terror, helplessness, impending doom
- Smothering or choking feeling, difficulty getting breath
- Dizziness or faintness
- Trembling
- Tingling, hot or cold spells
- Chest pain or discomfort
- Nausea
- Palpitation and rapid heart beat
- Sudden empty feeling in pit of stomach

Fear of places where attack occurs
